SPT-SZ 2500 deg² Survey (6% of sky)

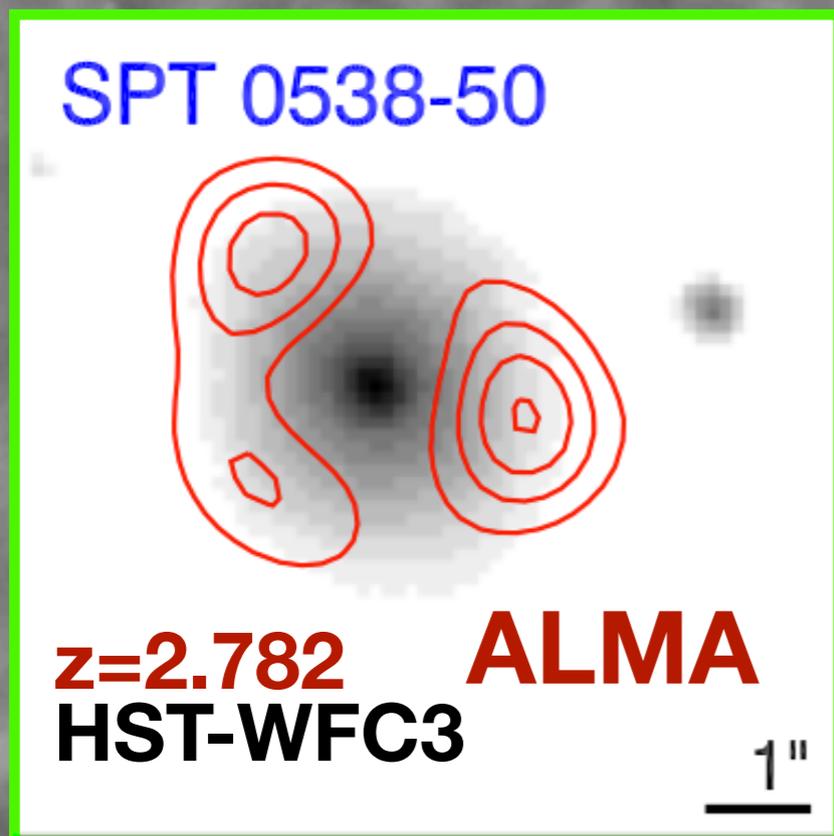

Status: finished in *Nov. 2011*.
Results shown today use all of this data.

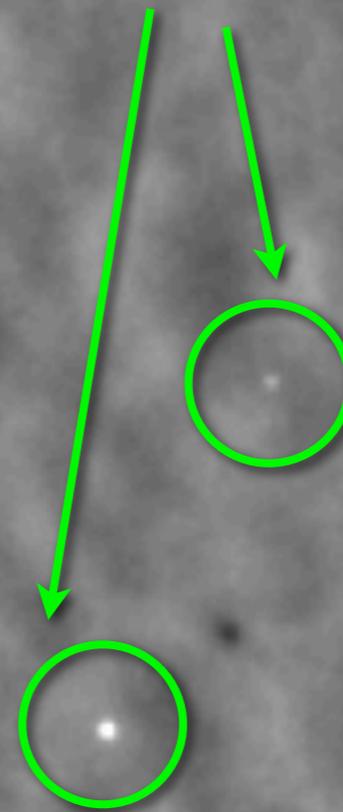

BRIEF DETOUR: What science can you do with this map?

Zoom in on an SPT map

~50 deg² from
2500 deg² survey

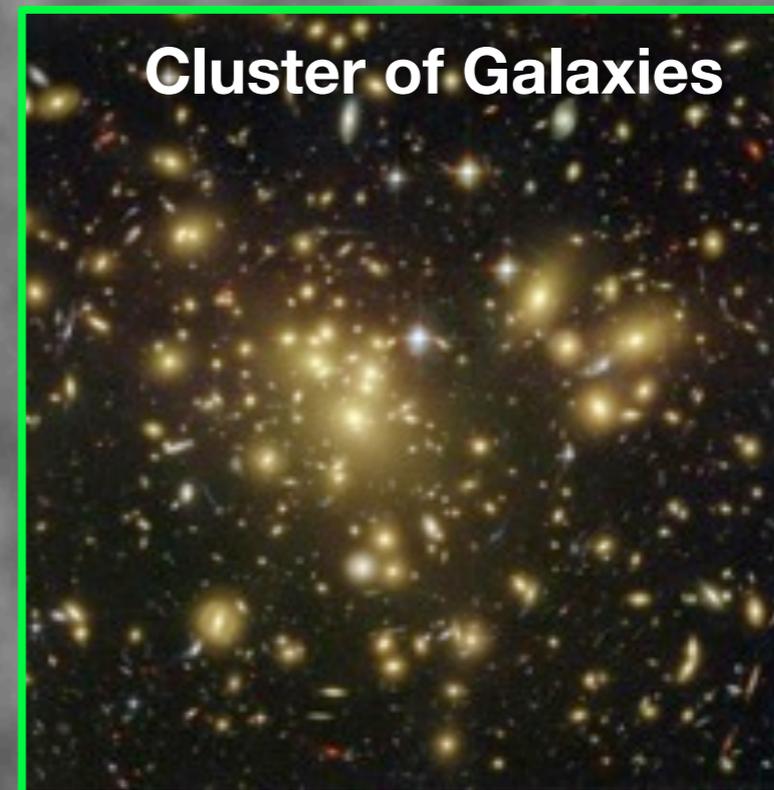

Radio and dusty galaxies show
up as bright spots

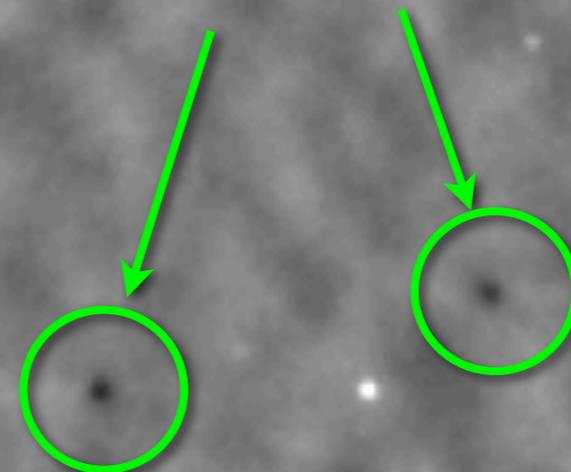

Zoom in on an SPT map

~50 deg² from
2500 deg² survey

High signal to noise Sunyaev-Zel'dovich (SZ) galaxy cluster detections as "shadows" against the CMB!

Zoom in on an SPT map

~50 deg² from
2500 deg² survey

Cosmic microwave
background (CMB)

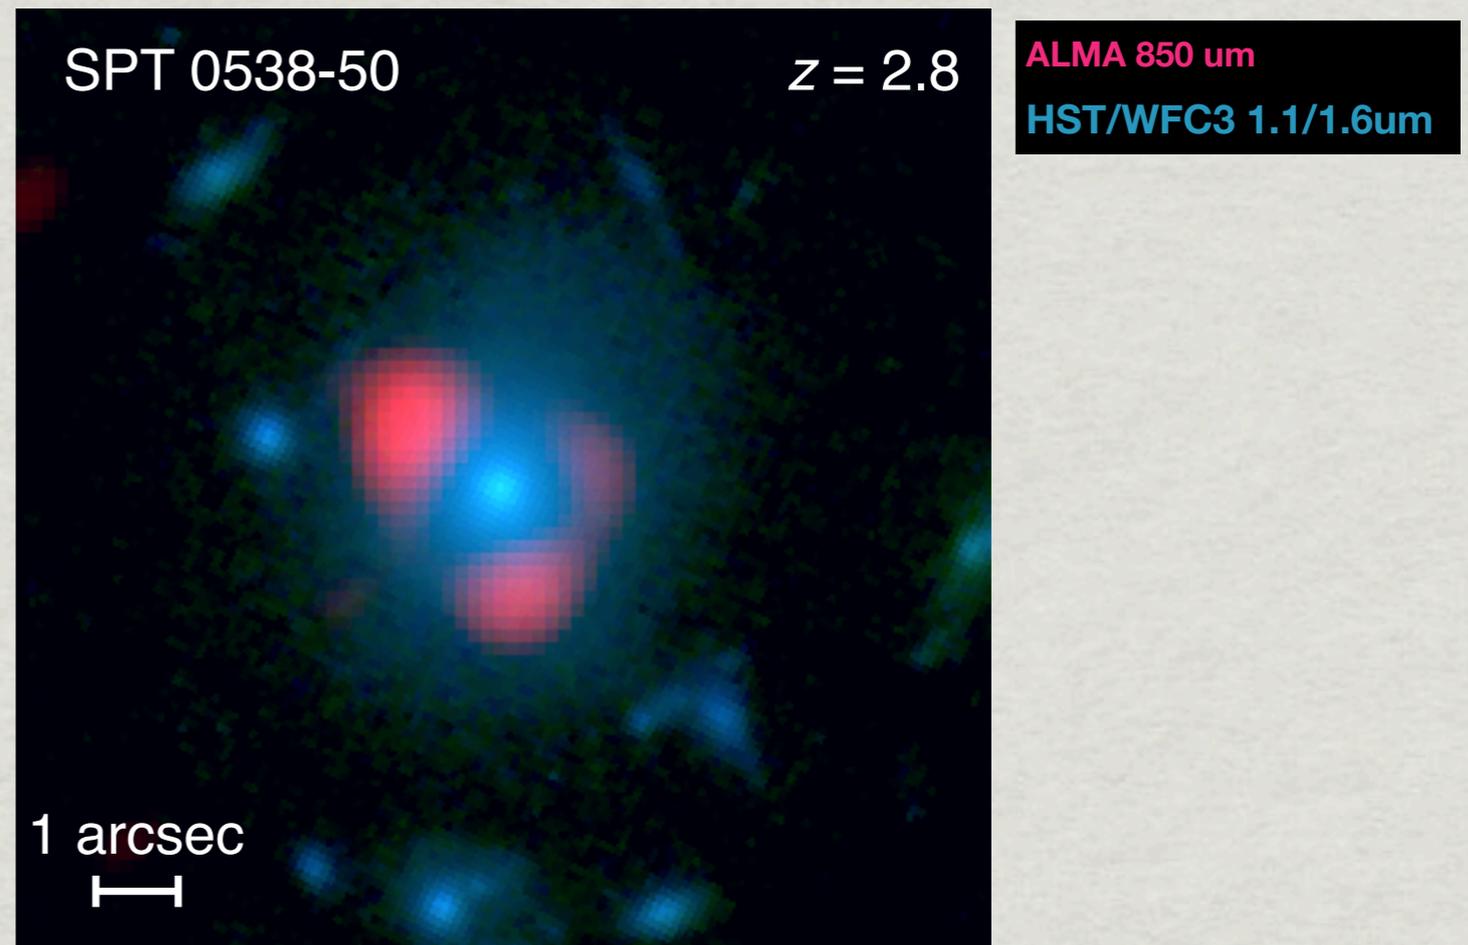

BRIEF DETOUR: There's a lot of other SPT science going on. Some examples:

- Emission from **high-z, dusty, star-forming galaxies** (individual & aggregate).

- Discovery of 100s of new massive **galaxy clusters** via thermal Sunyaev-Zel'dovich (SZ) Effect.

- Tight upper limits on diffuse **kinetic SZ**, and resulting constraints on **duration of reionization**.

...

$z=2.8$ star-forming galaxy discovered by SPT.

Galaxy image is lensed by $z=0.443$ foreground galaxy, as shown clearly by ALMA and HST/WFC3.

See Vieira et al. (0912.2338),
Mocanu et al. (1306.3470)

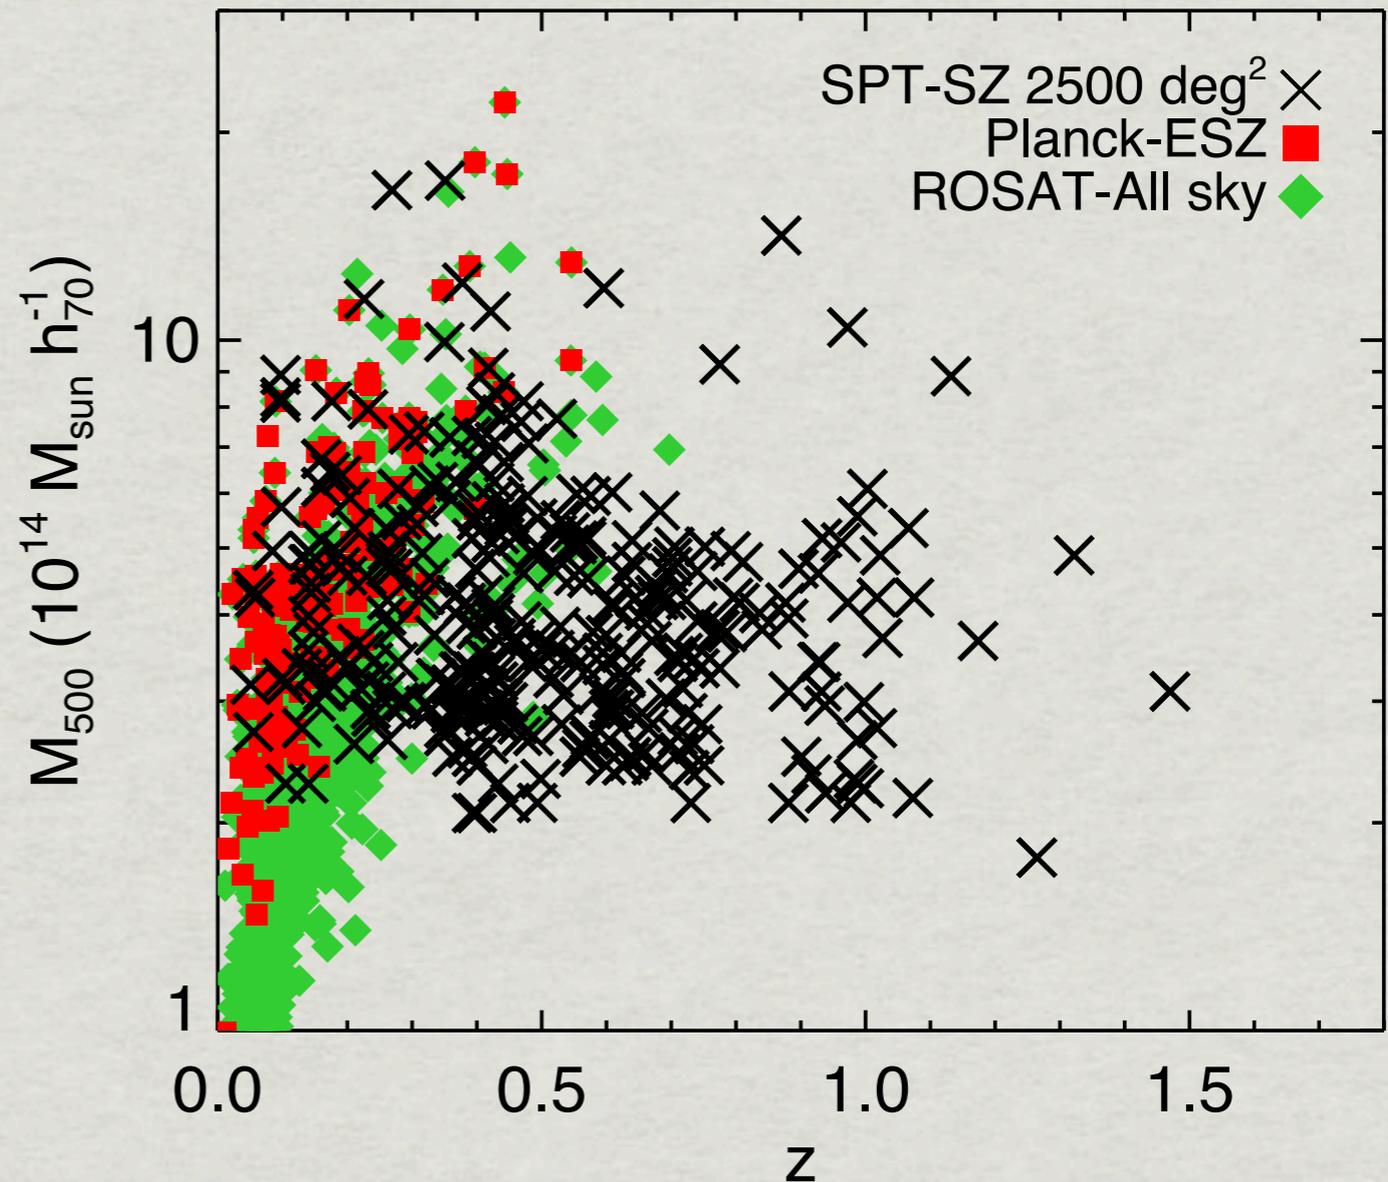

BRIEF DETOUR: There's a lot of other SPT science going on. Some examples:

3. The Future is Now: SPTpol and SPT-3G

n_s : spectral tilt

$$\Delta_R^2(k) = \Delta_R^2(k_0) \left(\frac{k}{k_0} \right)^{n_s - 1}$$

n_s generically departs from $n_s=1$ in inflationary models, because of lack of time-invariance of inflation.

n_s : spectral tilt

$$\Delta_R^2(k) = \Delta_R^2(k_0) \left(\frac{k}{k_0} \right)^{n_s - 1}$$

n_s generically departs from $n_s=1$ in inflationary models, because of lack of time-invariance of inflation.

$$n_s = 0.9623 \pm 0.0097 \quad (\text{SPT+WMAP})$$

3.9 σ preference for $n_s < 1$

$$n_s = 0.9538 \pm 0.0081 \quad (\text{SPT+WMAP+H0+BAO})$$

5.7 σ preference for $n_s < 1$

(first $>5\sigma$ preference for $n_s < 1$)

quick detour: H0 and BAO data

H0

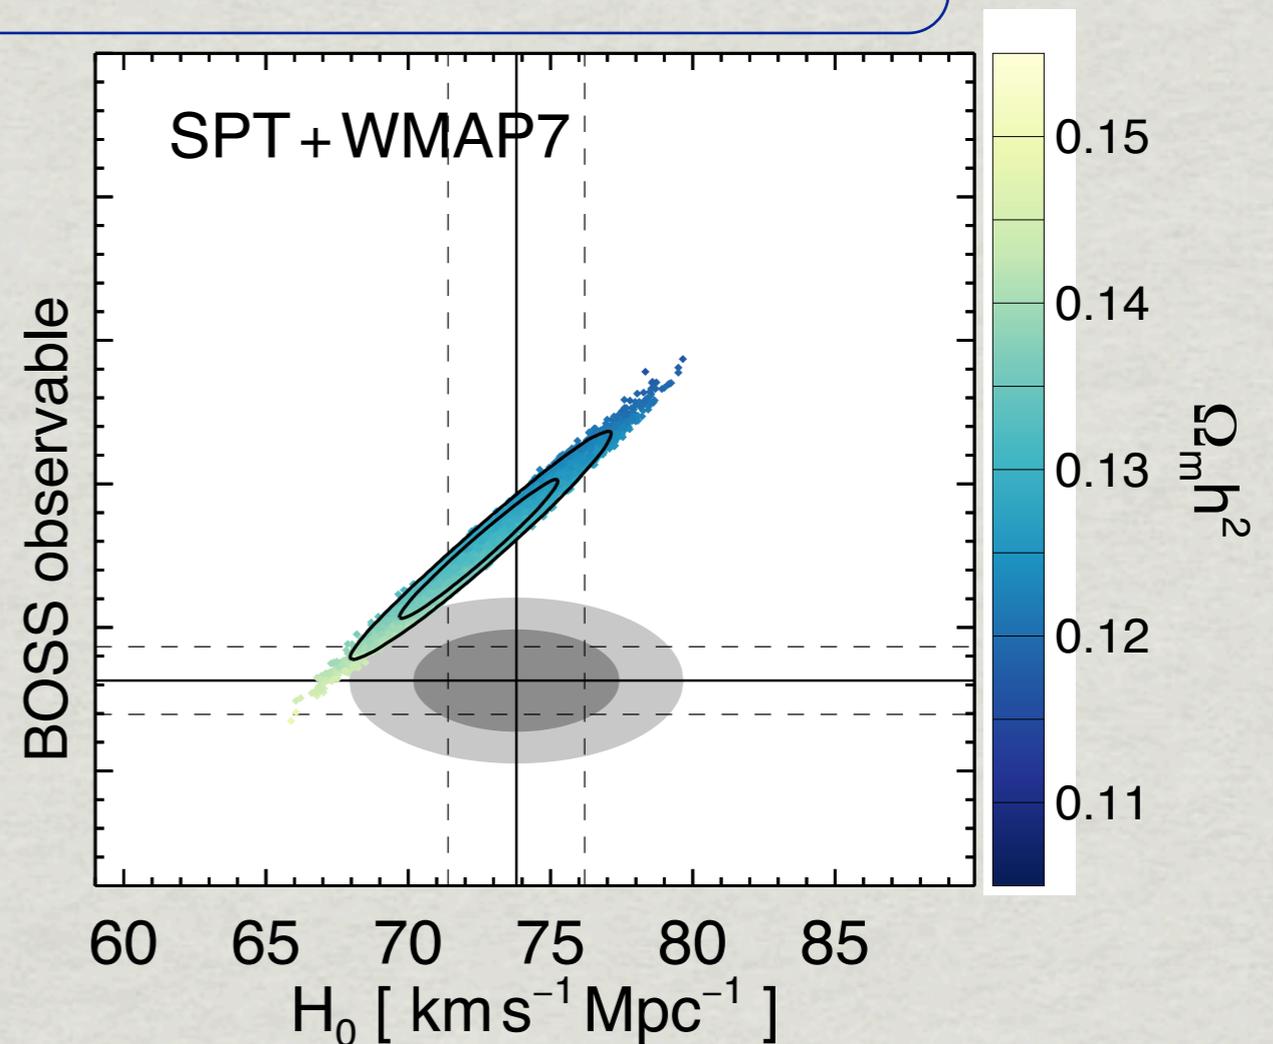

Riess et al 2011

BAO

BOSS (z=0.57), Anderson et al 2012
SDSS (z=0.35), Padmanabhan et al 2012
WiggleZ (z=0.44-0.73), Blake et al 2011

There is some ~ 2 -sigma tension between CMB, H0, and BAO.

This is true in LCDM, and in most other models.

(see Hou, Reichardt, KTS, Follin, Keisler, et al, 1212.7231)

n_s : spectral tilt

$$\Delta_R^2(k) = \Delta_R^2(k_0) \left(\frac{k}{k_0} \right)^{n_s - 1}$$

n_s generically departs from $n_s=1$ in inflationary models, because of lack of time-invariance of inflation.

$$n_s = 0.9623 \pm 0.0097 \quad (\text{SPT+WMAP})$$

3.9 σ preference for $n_s < 1$

$$n_s = 0.9538 \pm 0.0081 \quad (\text{SPT+WMAP+H0+BAO})$$

5.7 σ preference for $n_s < 1$

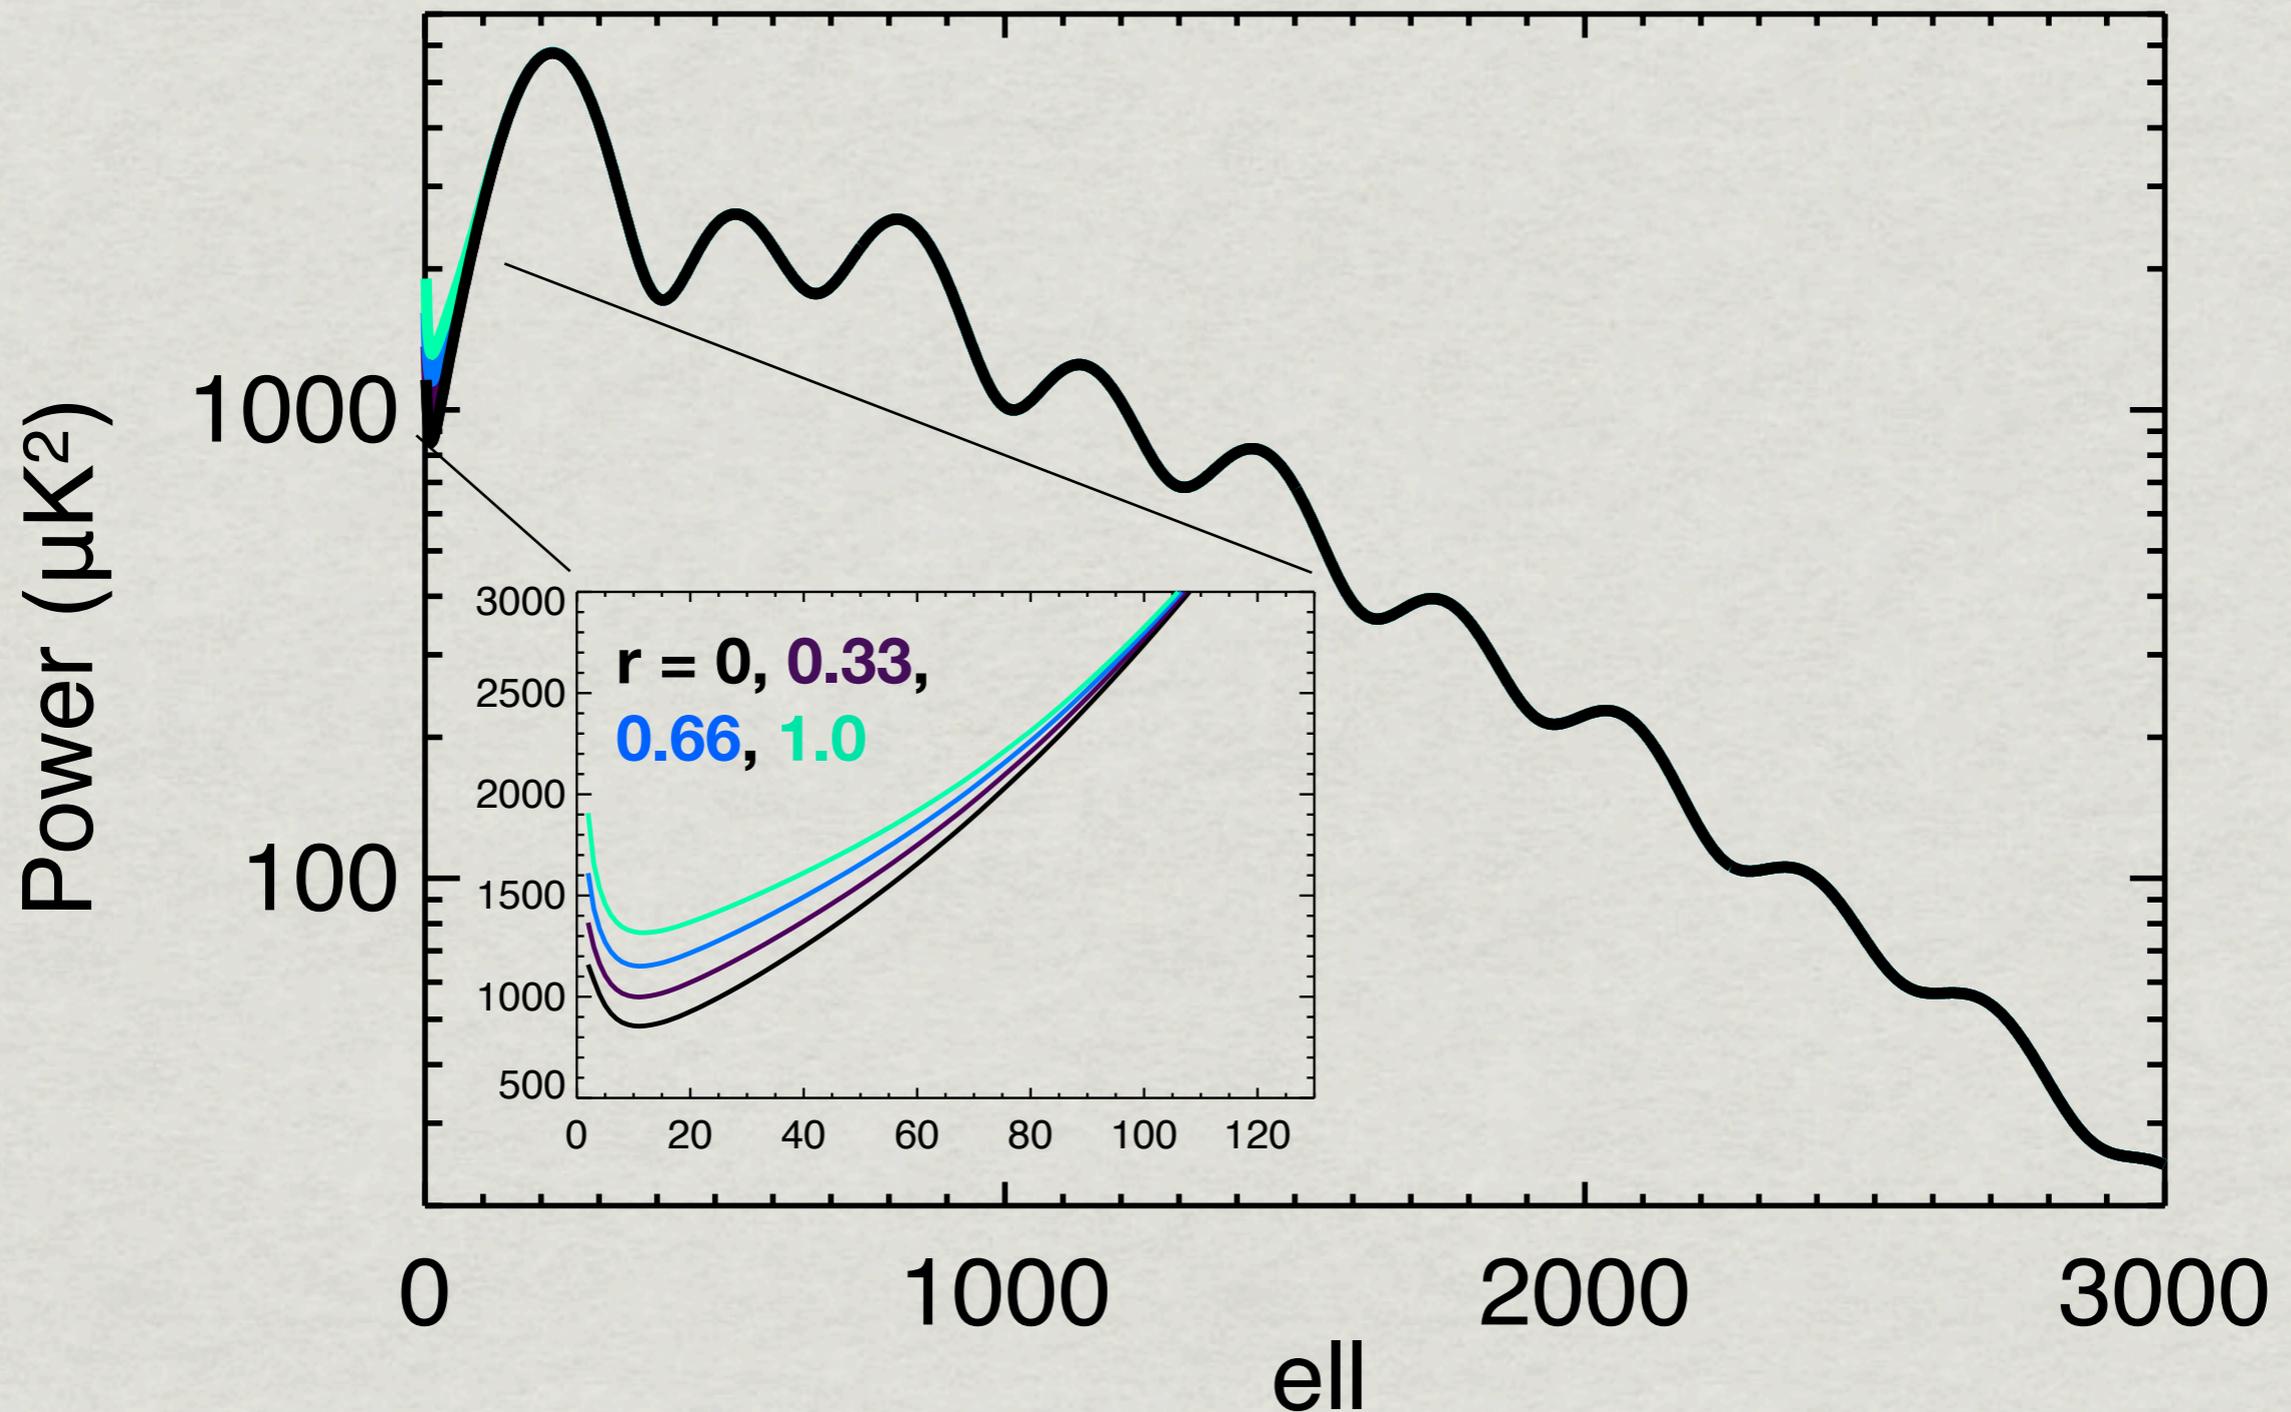

(first $>5\sigma$ preference for $n_s < 1$)

r: tensor power

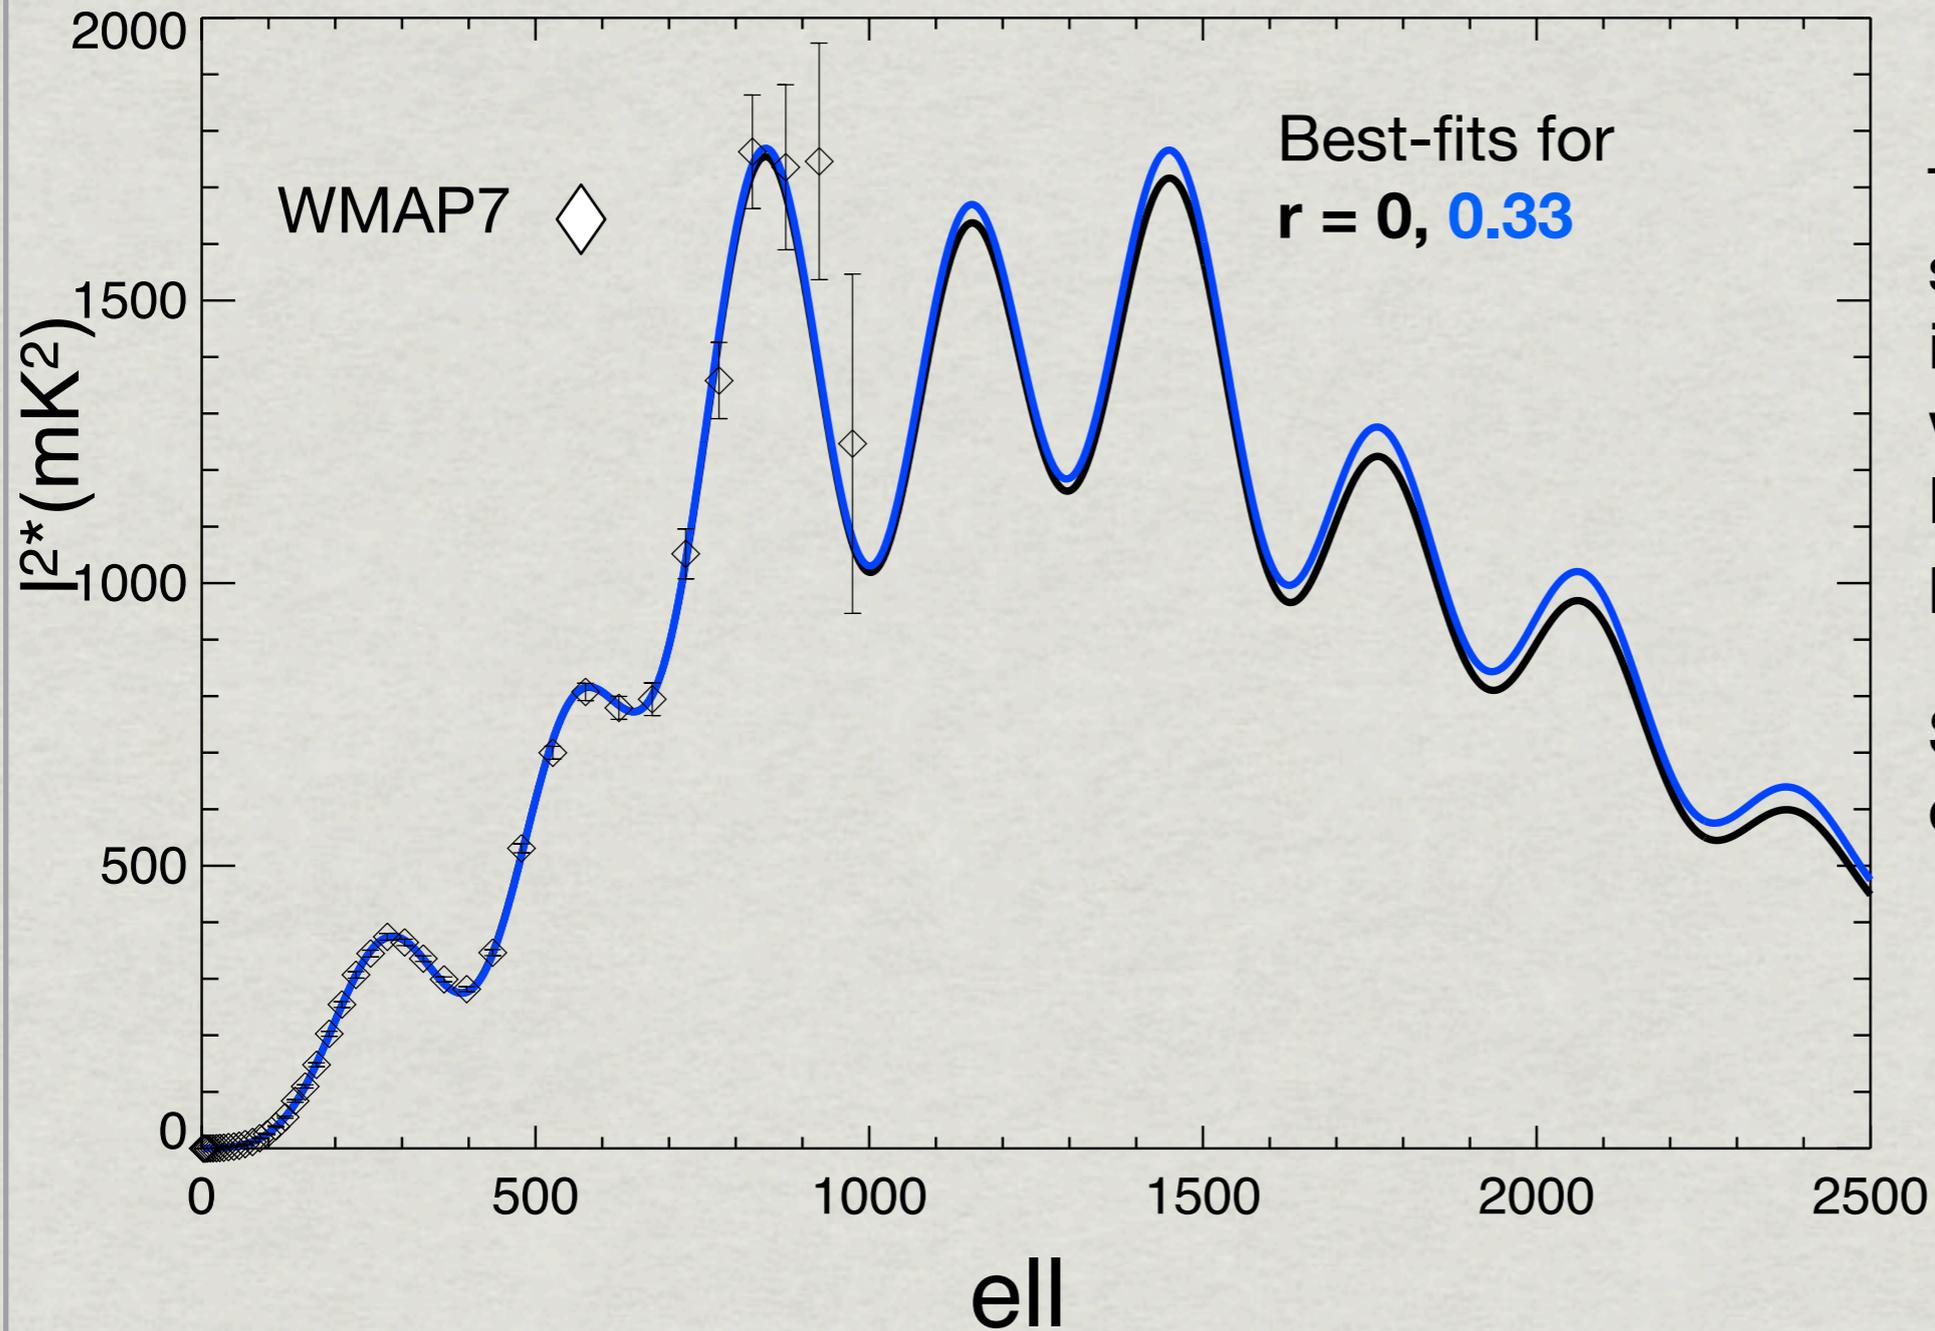

$$\Delta_h^2(k) = \Delta_h^2(k_0) \left(\frac{k}{k_0} \right)^{n_t}, \quad \text{(tensor/scalar) ratio } r \equiv \frac{\Delta_h^2}{\Delta_R^2}$$

Tensor power can be generated from inflationary gravitation waves, and a detection of $r > 0$ could provide a handle on the energy scale of inflation.

Tensor perturbations and temperature anisotropy

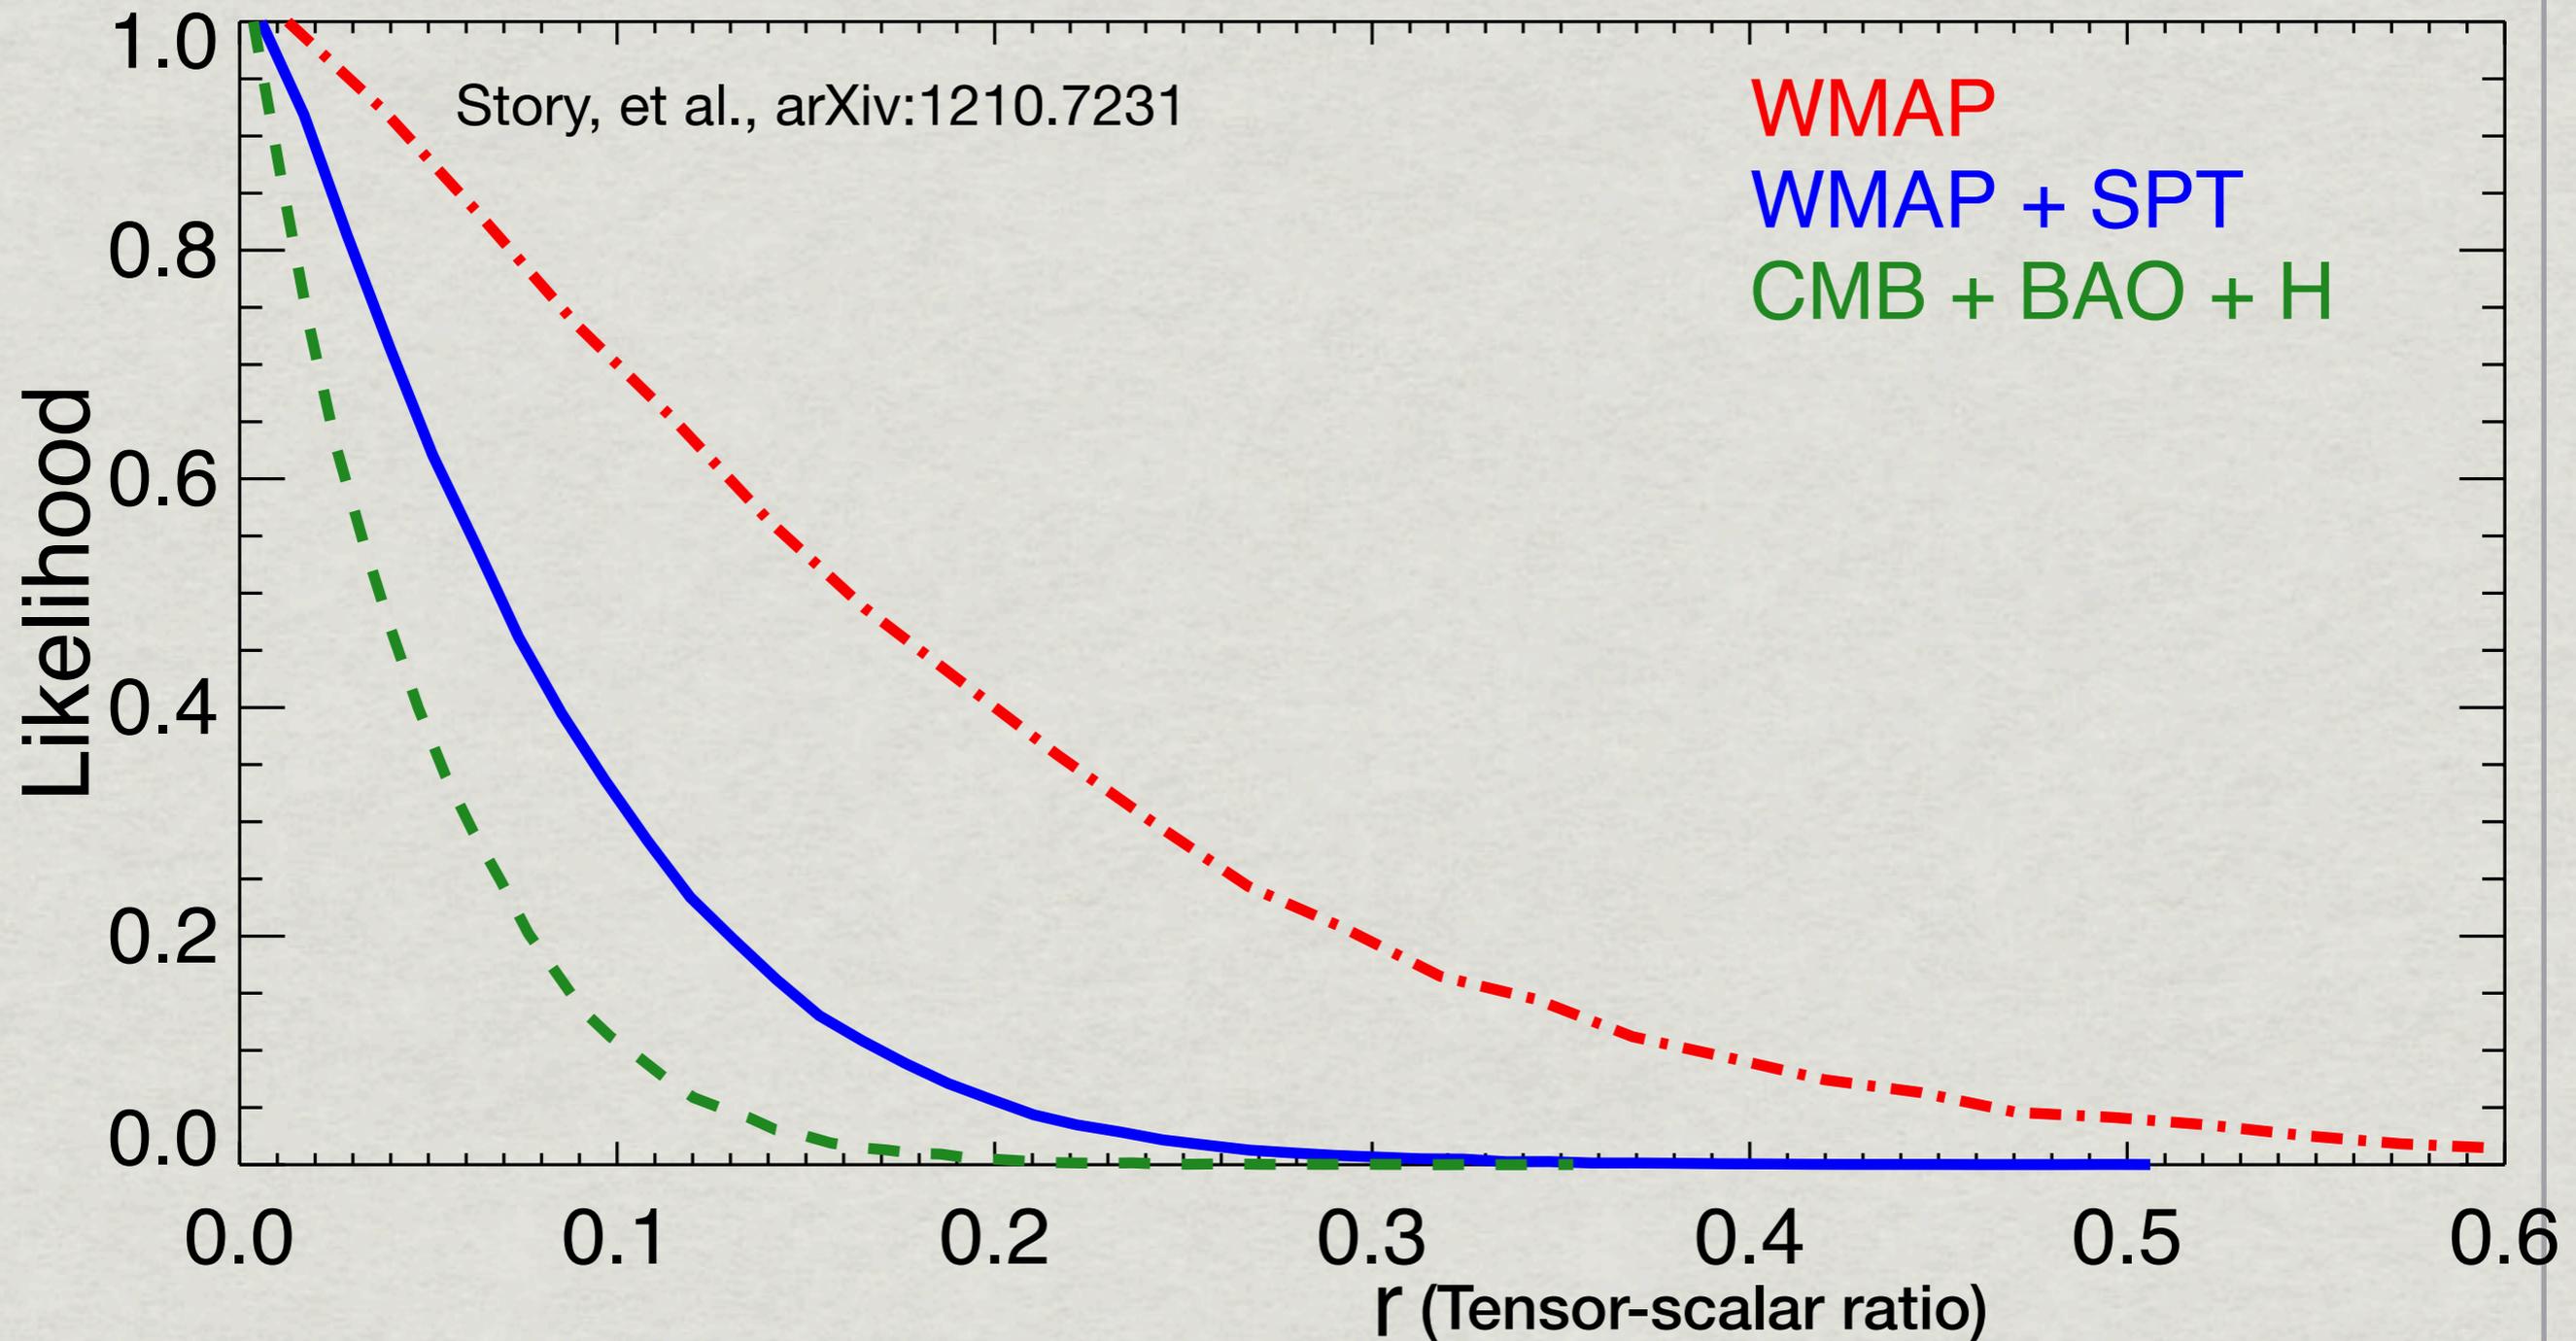

Role of small-scale data

Tensors only affect large scales, but their impact is partially degenerate with the scalar power law slope (n_s) and other parameters.

Small-scale data help disentangle the two.

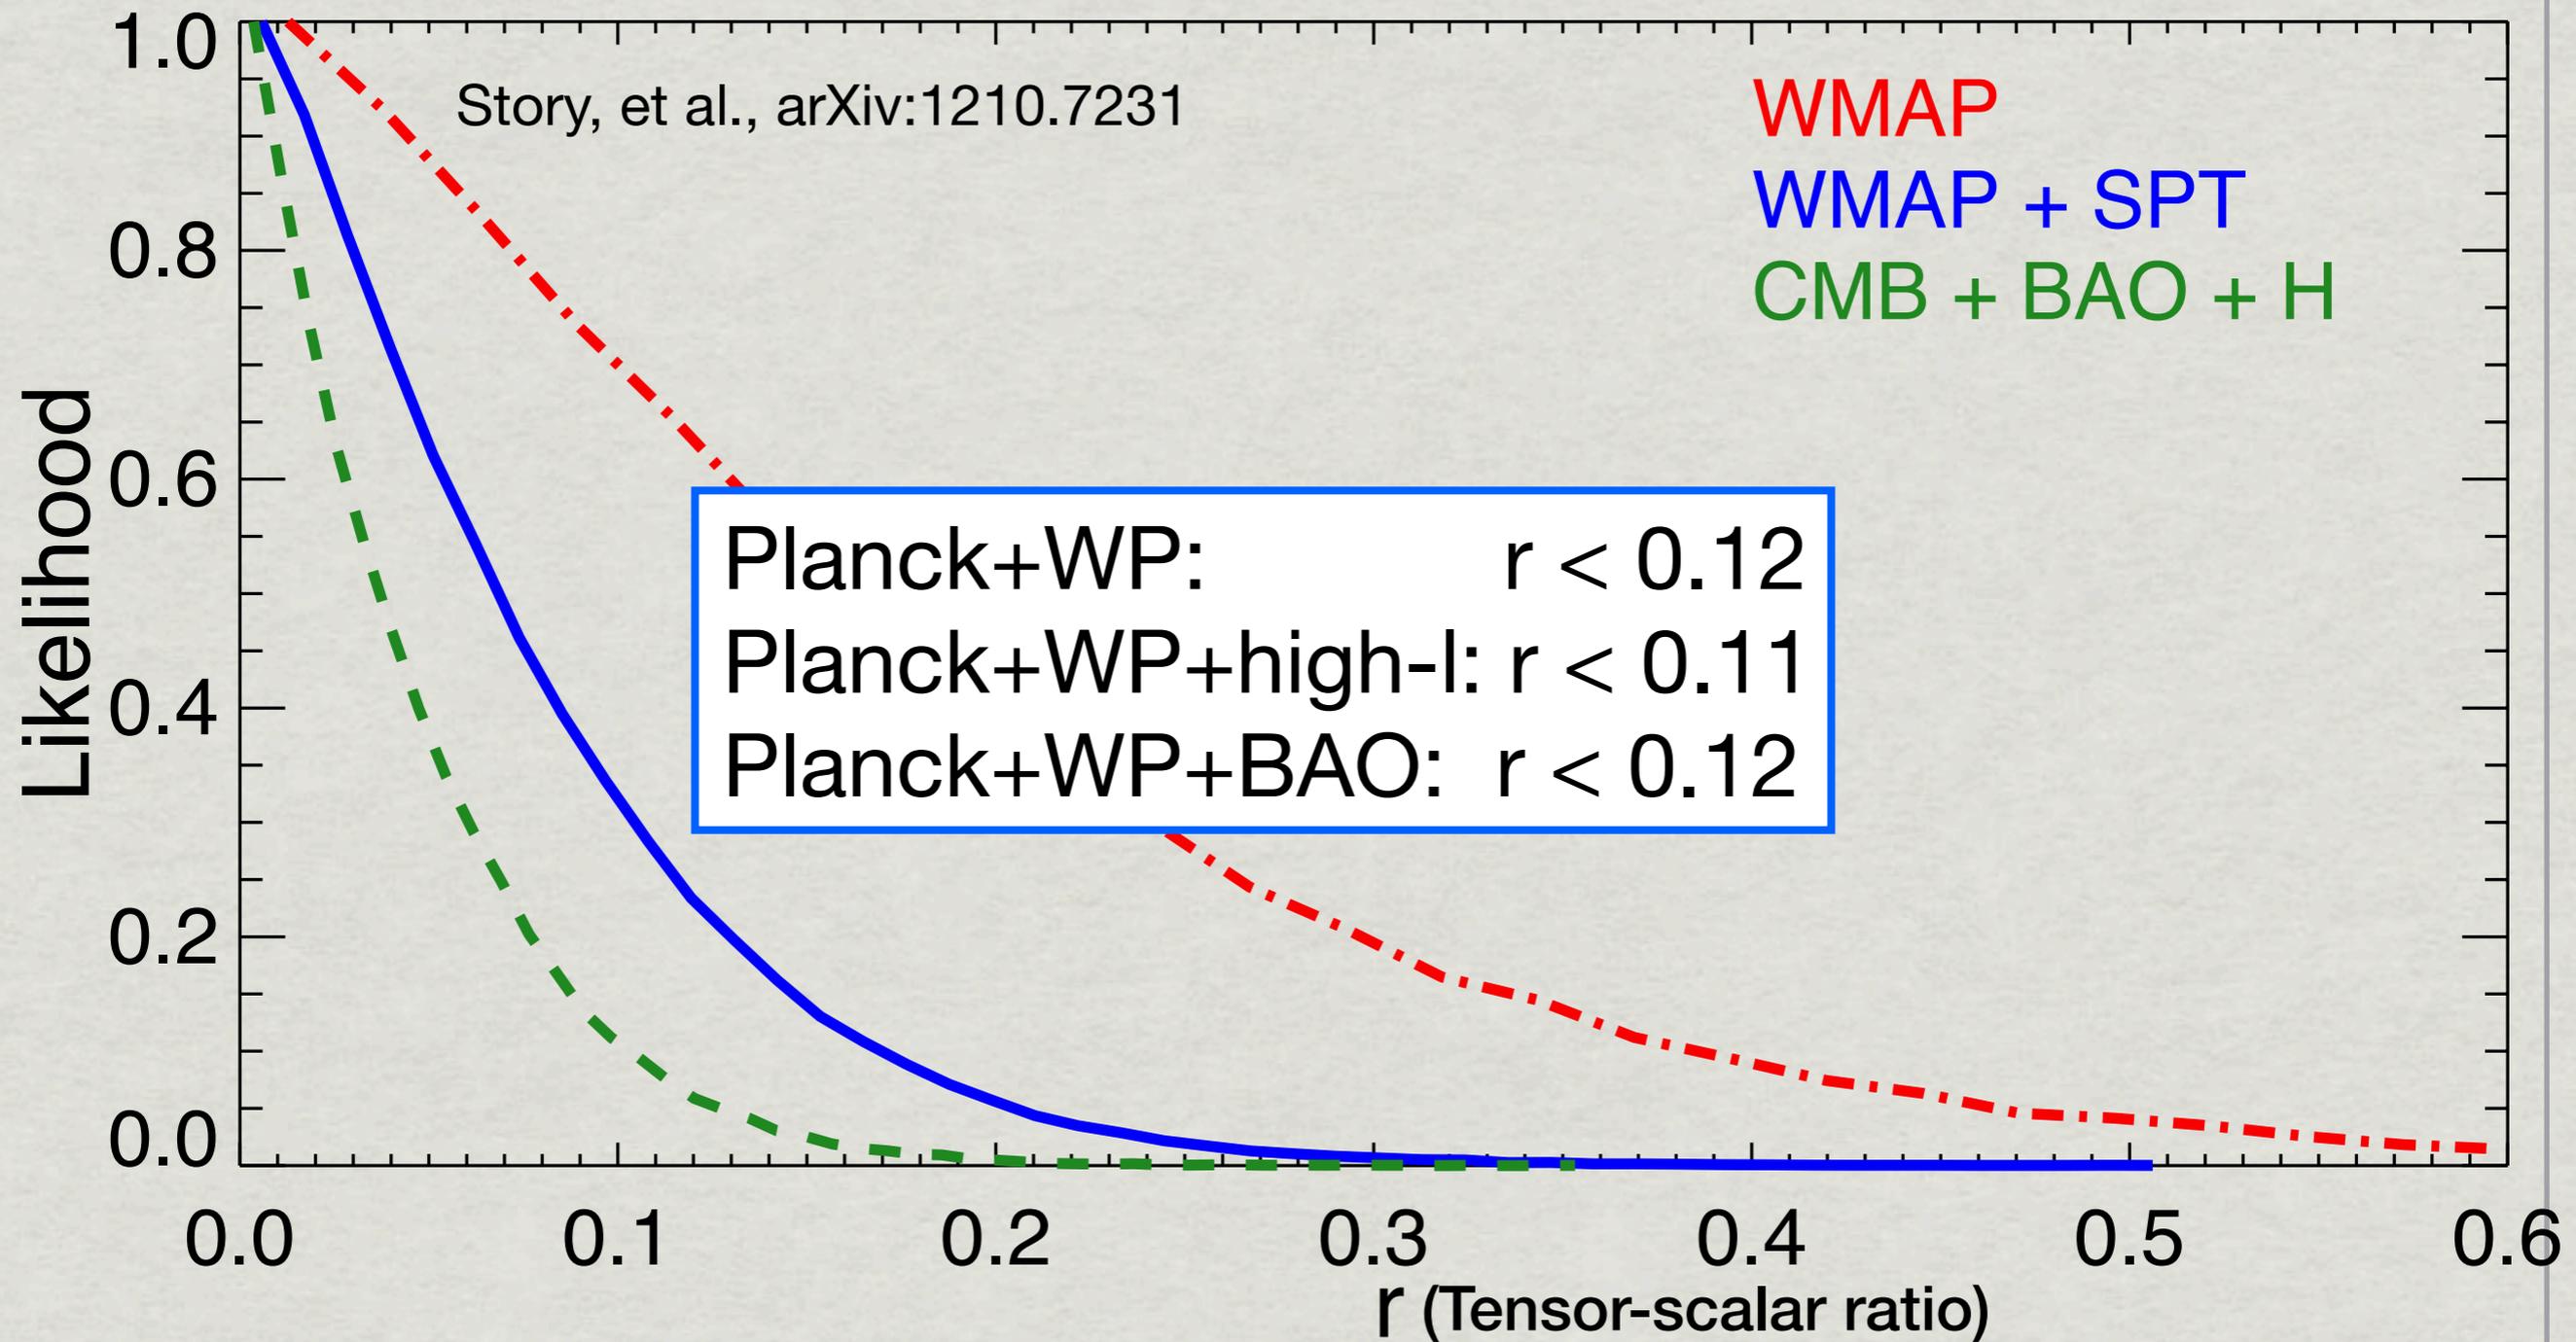

Hitting TT sample variance limit

No evidence for tensors yet; 95% upper limits are:

WMAP: $r < 0.36$ **WMAP+SPT: $r < 0.18$** **CMB+BAO+H0: $r < 0.11$**

Planck - same limits internally

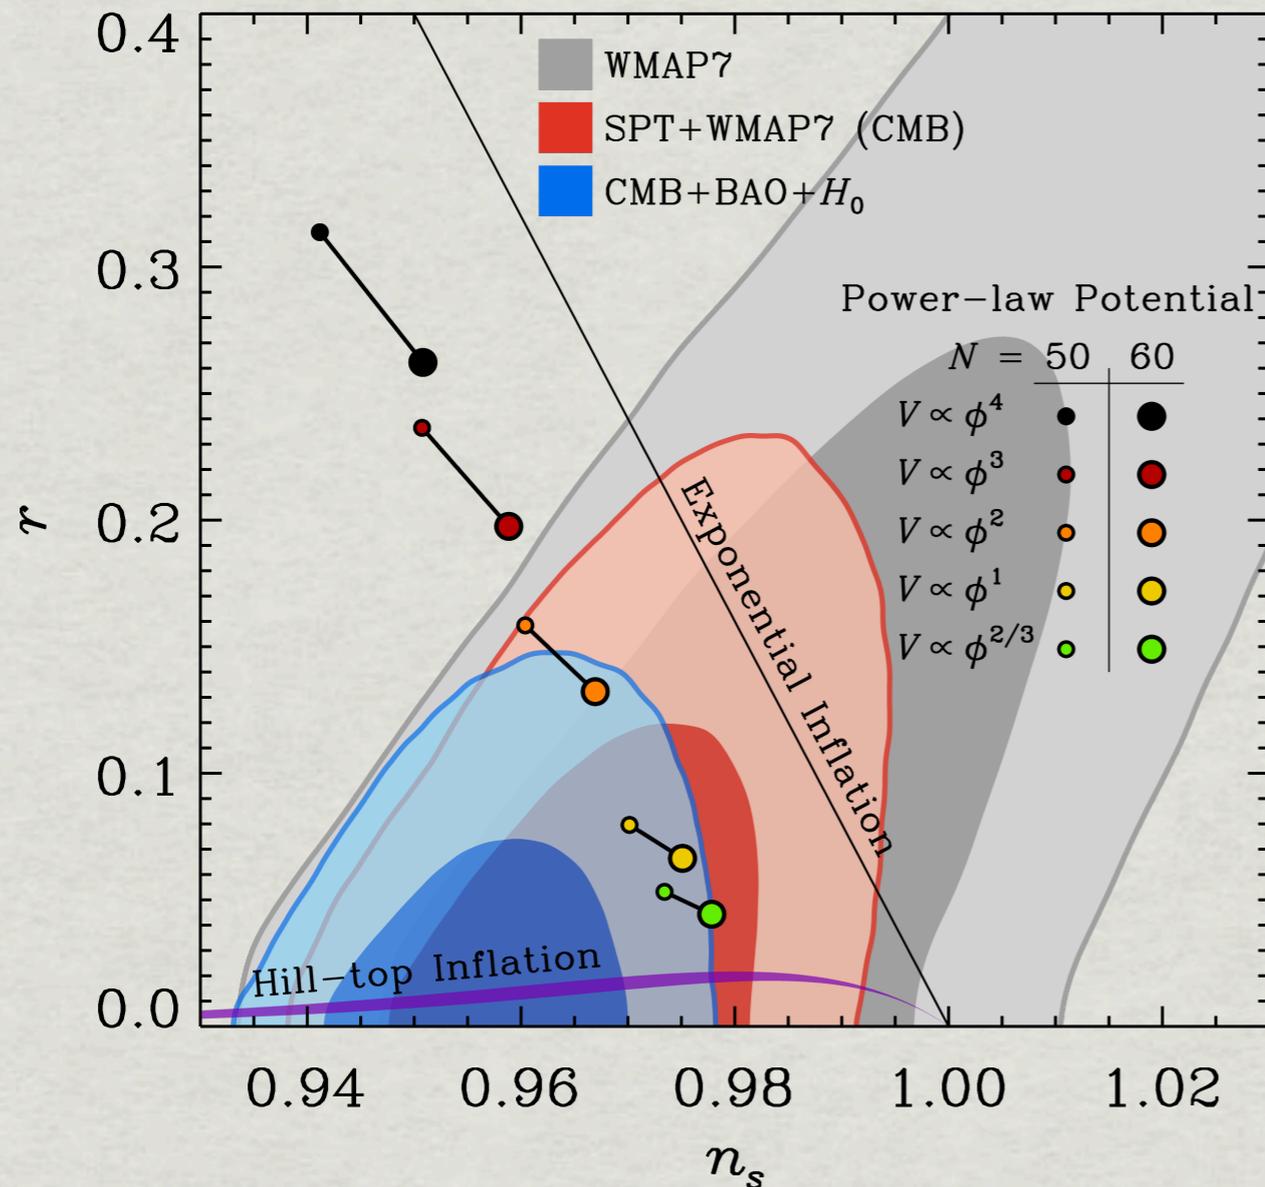

No evidence for tensors yet; 95% upper limits are:

WMAP: $r < 0.36$ **WMAP+SPT: $r < 0.18$** **CMB+BAO+H0: $r < 0.11$**

n_s VS r

Use data to constrain some simple cases of single-field, slow-roll inflation, based on their predictions for relationship between n_s and r .

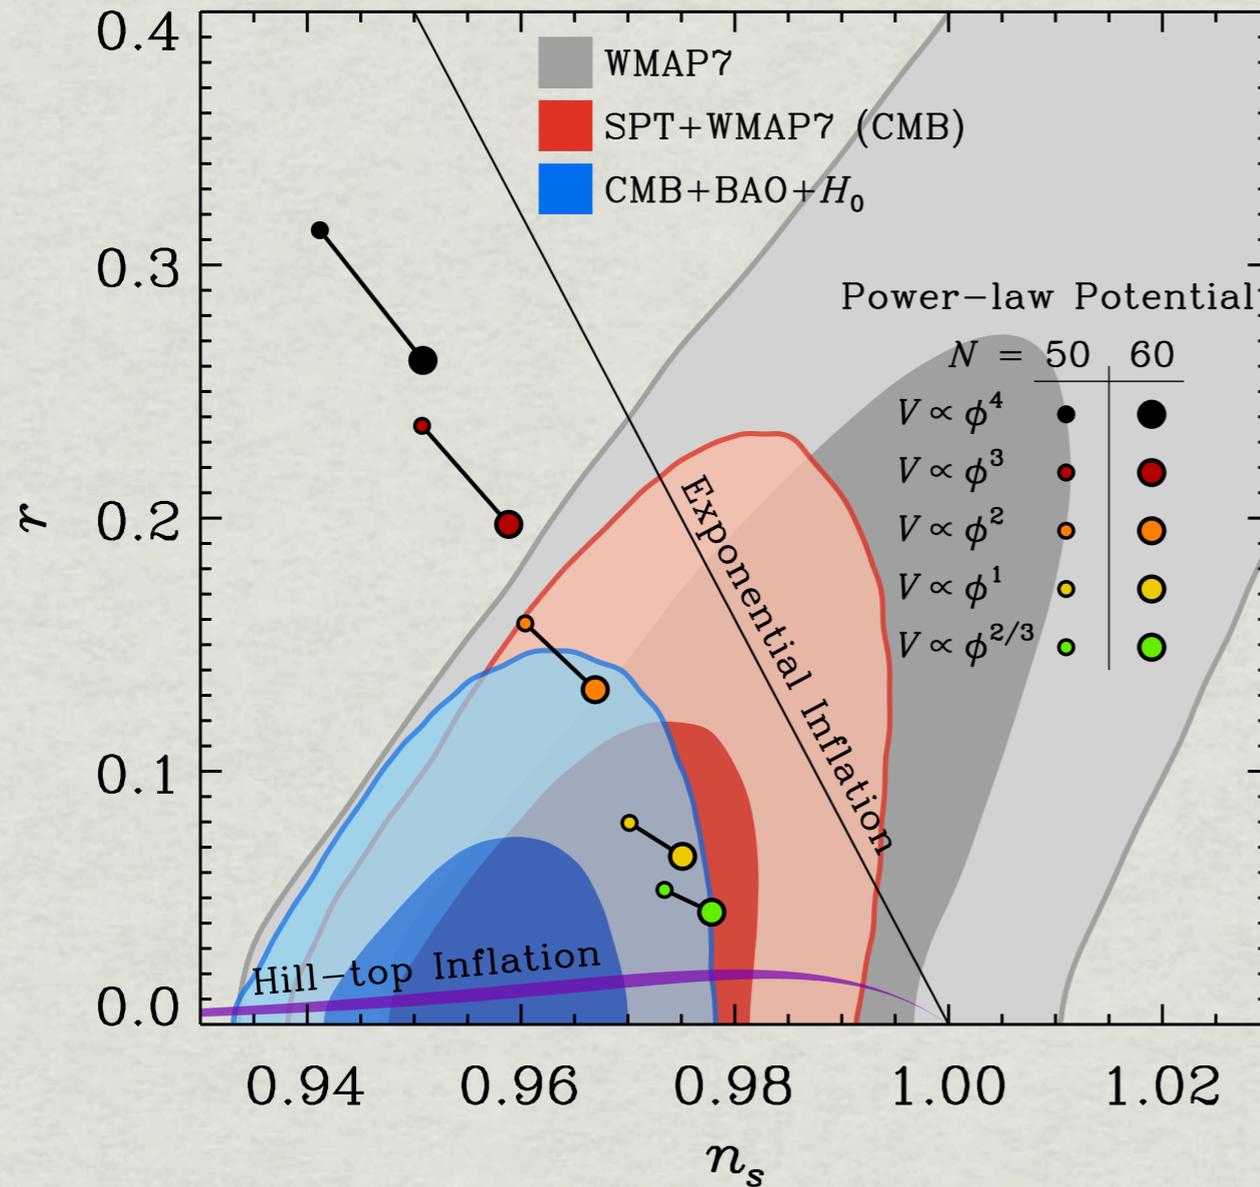

These constraints put pressure on models of inflation.

We are hitting the TT sample variance limit.

Figure by Brent Follin, UC Davis

n_s VS r

Use data to constrain some simple cases of single-field, slow-roll inflation, based on their predictions for relationship between n_s and r .

SPT constraints on inflation are consistent with those from Planck

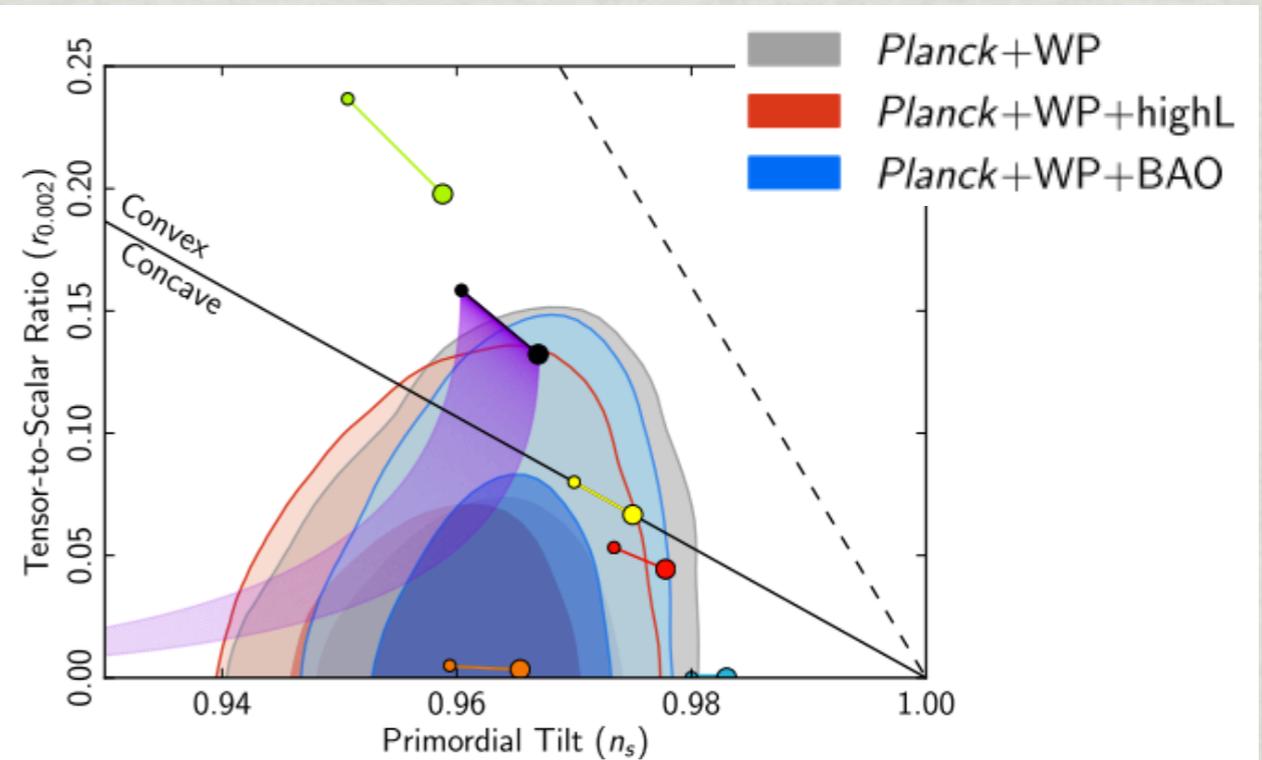

Figure by Brent Follin, UC Davis

Take Away #1

Detected departure from scale invariance ($n_s < 1$) at $> 5\sigma$.

We are hitting the TT sample variance limit on constraints on r (need CMB Polarization measurements to go further)

Outline

1. Overview of SPT

2. Results from SPT:

- SPT data
- primordial power spectra (inflation)
- massive neutrinos
- gravitational lensing of CMB

3. The Future is Now: SPTpol and SPT-3G

Massive Neutrinos

From neutrino oscillations experiments, we know neutrinos have mass. These experiments measure *mass differences* $(\Delta m)^2$, but what is the *absolute mass*?
Related question: what's the *mass hierarchy*?

From oscillation expt's and double-beta decay expt's, we know:

$$0.06 \text{ eV} \leq \Sigma m_\nu \leq 1.8 \text{ eV}$$

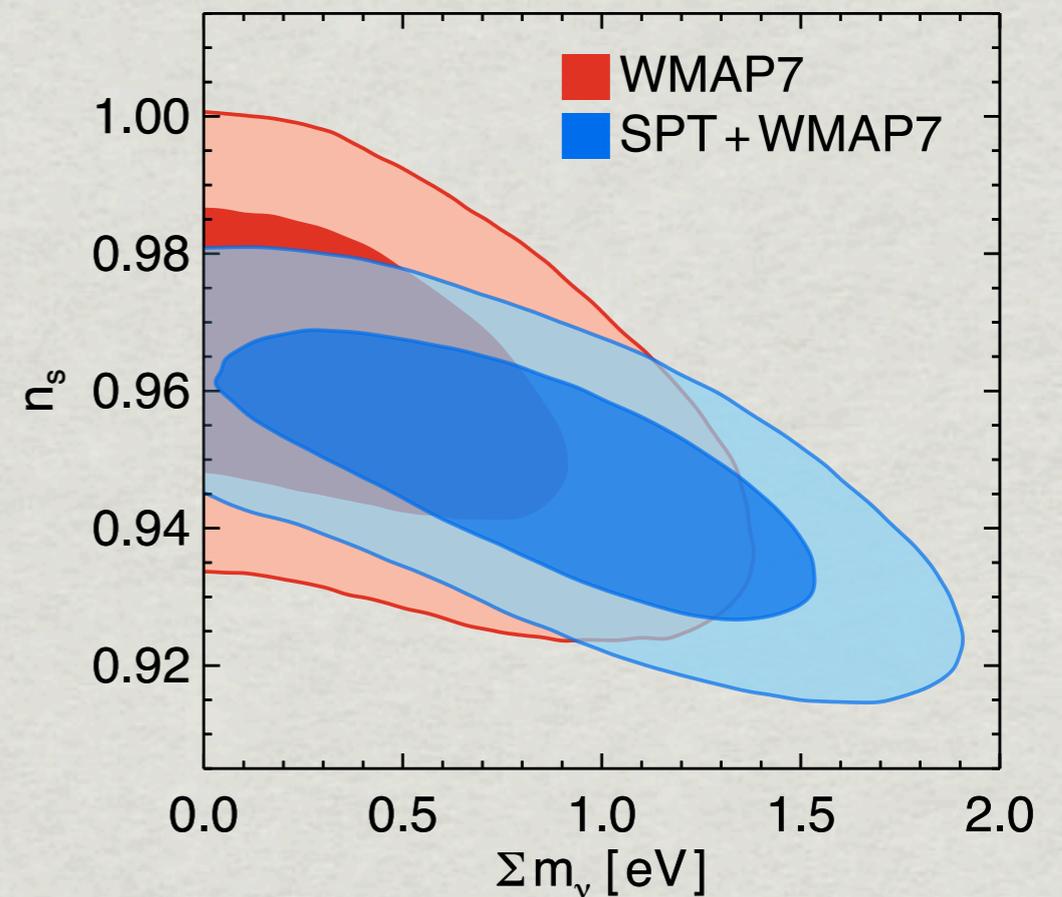

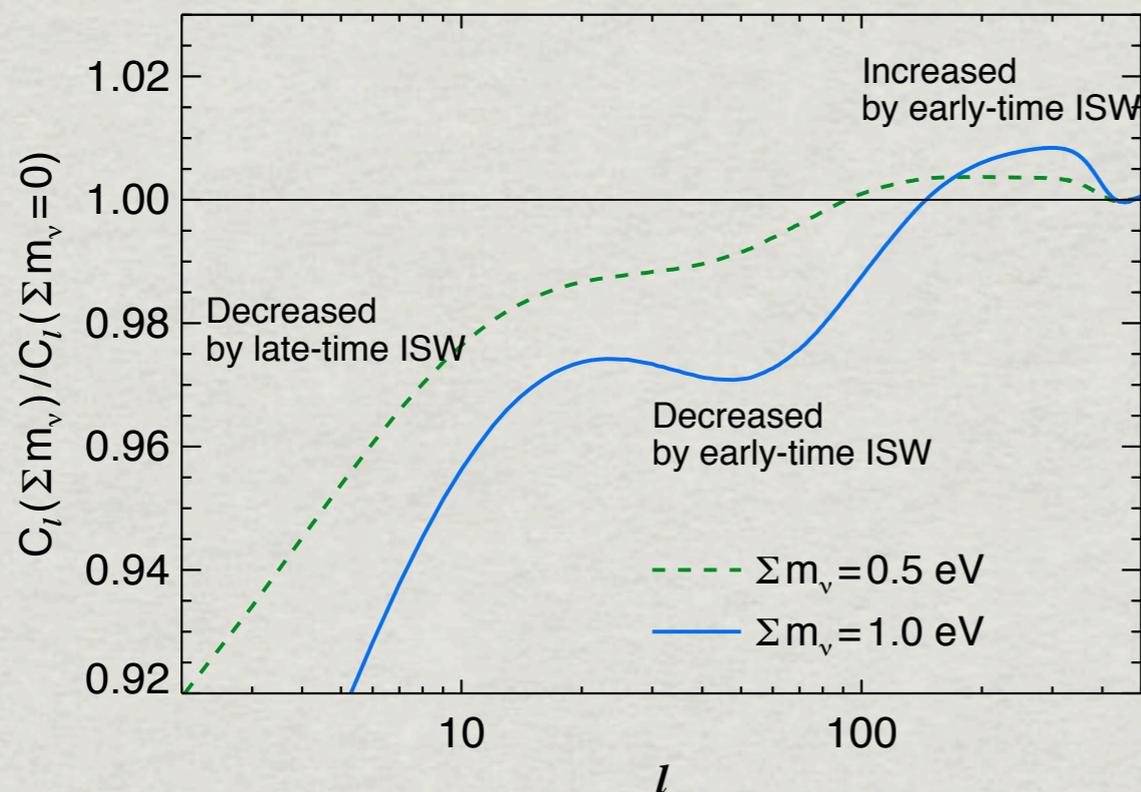

What can we learn from cosmology, which is sensitive primarily to Σm_ν , as opposed to $(\Delta m)^2$?

CMB+ constraints on massive ν 's

CMB data are sensitive to neutrino mass through the early ISW effect and associated parameters degeneracies.

BAO/H0 are sensitive to the late-time expansion rate, which depends on the neutrino contribution to the energy density.

Measures of low-redshift growth (CMB lensing, Clusters, LRGs) are sensitive to neutrino mass through its effect on the matter power spectrum.

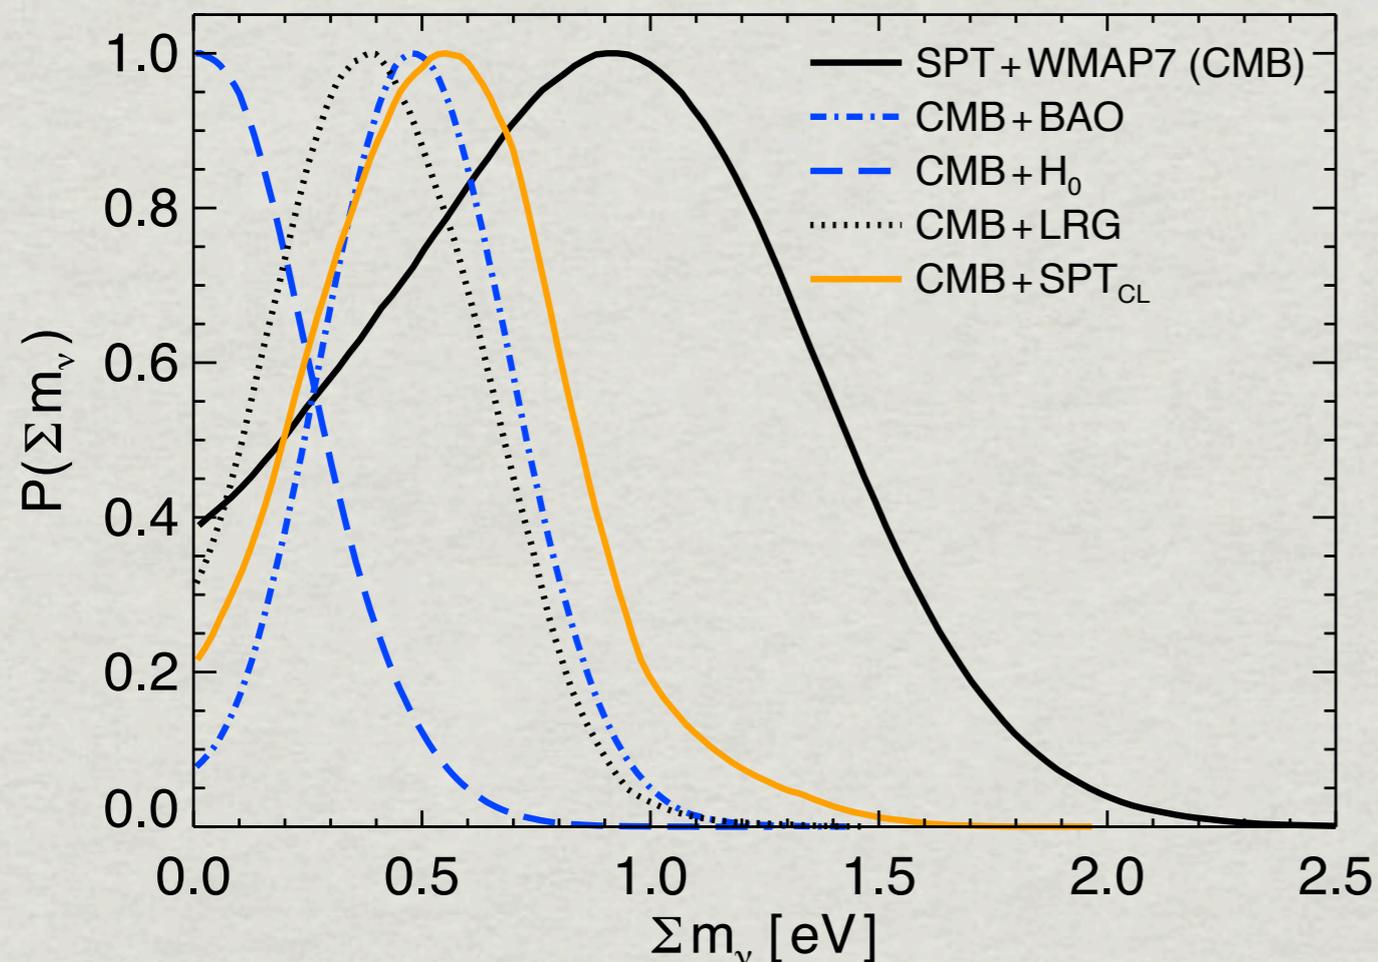

(see Hou, Reichardt, KTS, Follin, Keisler, et al, 1212.7231)

CMB+ constraints on massive ν 's

CMB data are sensitive to neutrino mass through the early ISW effect and associated parameters degeneracies.

BAO/ H_0 are sensitive to the late-time expansion rate, which depends on the neutrino contribution to the energy density.

Measures of low-redshift growth (CMB lensing, Clusters, LRGs) are sensitive to neutrino mass through its effect on the matter power spectrum.

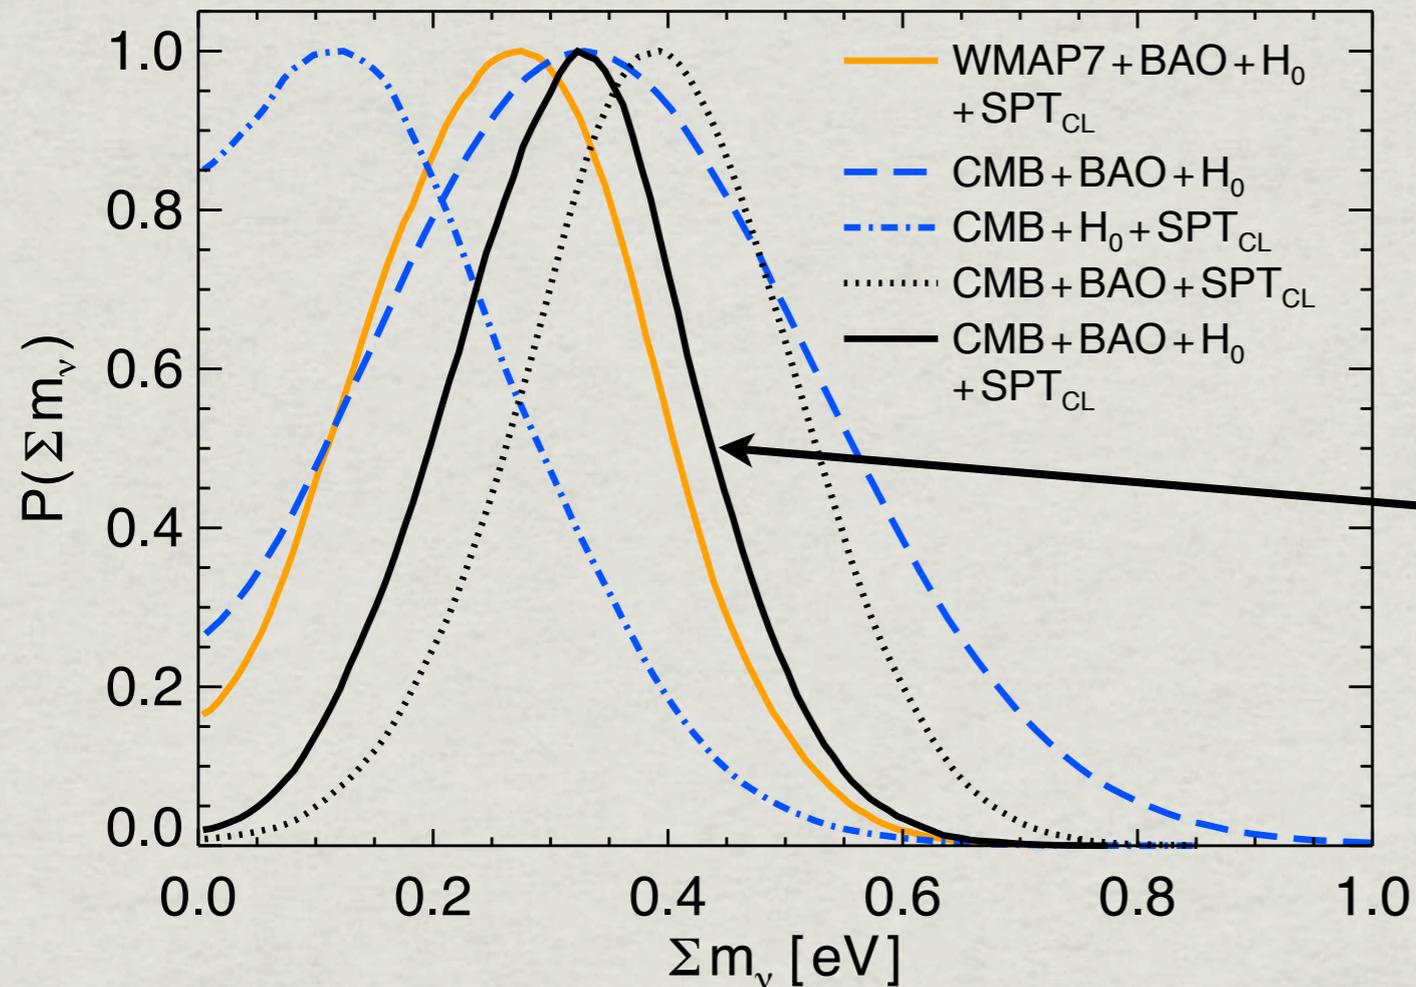

SPT+WMAP (CMB) prefers massive neutrinos at $\sim 1\sigma$.

BAO data add $\sim 1\sigma$.

SPT_clusters add another $\sim 1\sigma$.

CMB++ constraints on massive nu's

CMB+BAO+H0+SPT_CL yields

$$\Sigma m = (0.32 \pm 0.11) \text{ eV}$$

a **3 σ** preference for $\Sigma m > 0$.

Remains at $>2\sigma$ if you drop only clusters.

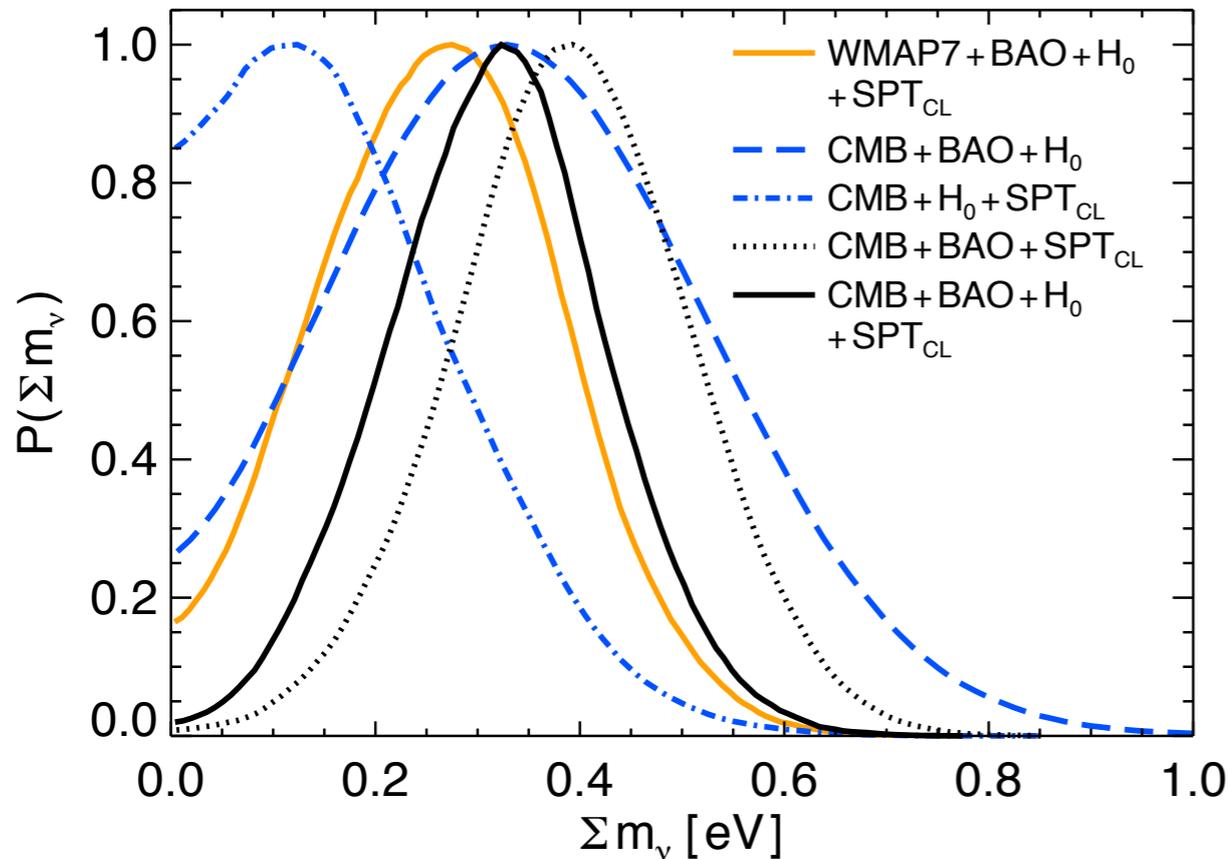

Drops to $>1\sigma$ if you drop only BAO.

There are data combinations that yield a 3σ “detection” of non-zero neutrino mass, at ~ 0.3 eV or $\sim 6X$ the minimum Σm .

Will this hold up with future CMB/BAO/H0/LSS data?

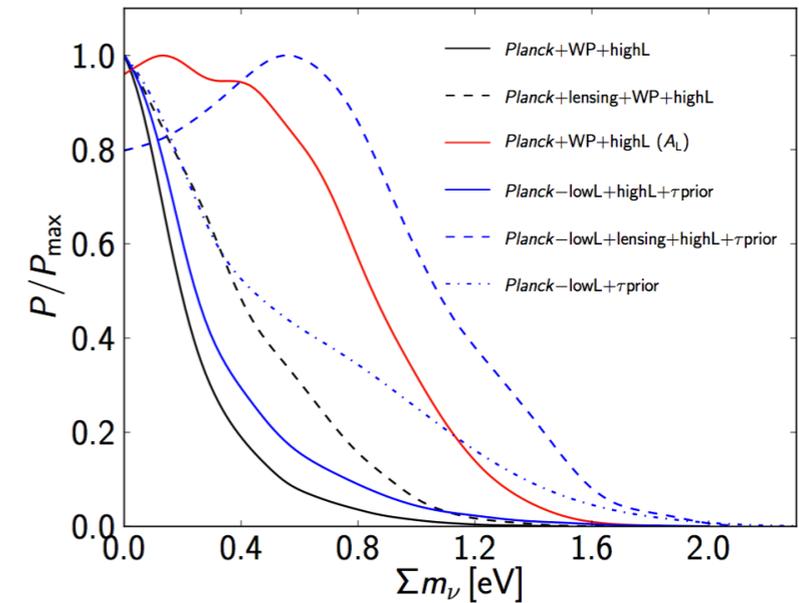

CMB++ constraints on massive nu's

SPT++

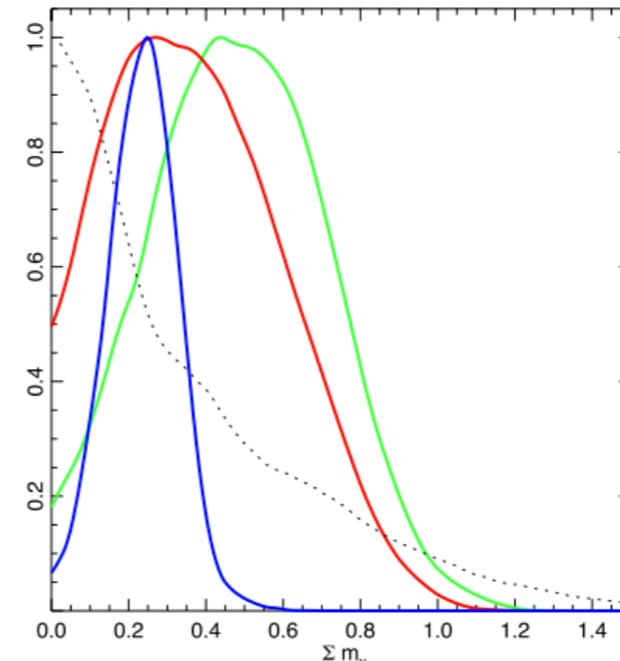

$\Sigma m = (0.32 \pm 0.11) \text{ eV}$
CMB+BAO+H0+SPT_CL

Planck++

$\Sigma m < 0.23 \text{ eV}$
Planck+WP+highL+BAO

$\Sigma m = 0.22 \pm 0.09 \text{ eV}$
Planck+BAO+Clusters

Planck++ data prefer less massive neutrinos:

- combining H0 with BAO prefers massive neutrinos
- Planck observes *stronger* gravitational lensing of the CMB, implying more clustering, and *lower* neutrino mass.
- Planck++ constraints do not include Clusters

Take Away #2

CMB data is sensitive to Σm_ν through the early ISW effect.

CMB++ data from the SPT prefer $\Sigma m_\nu > 0$ at $\sim 3\sigma$.

Outline

1. Overview of SPT

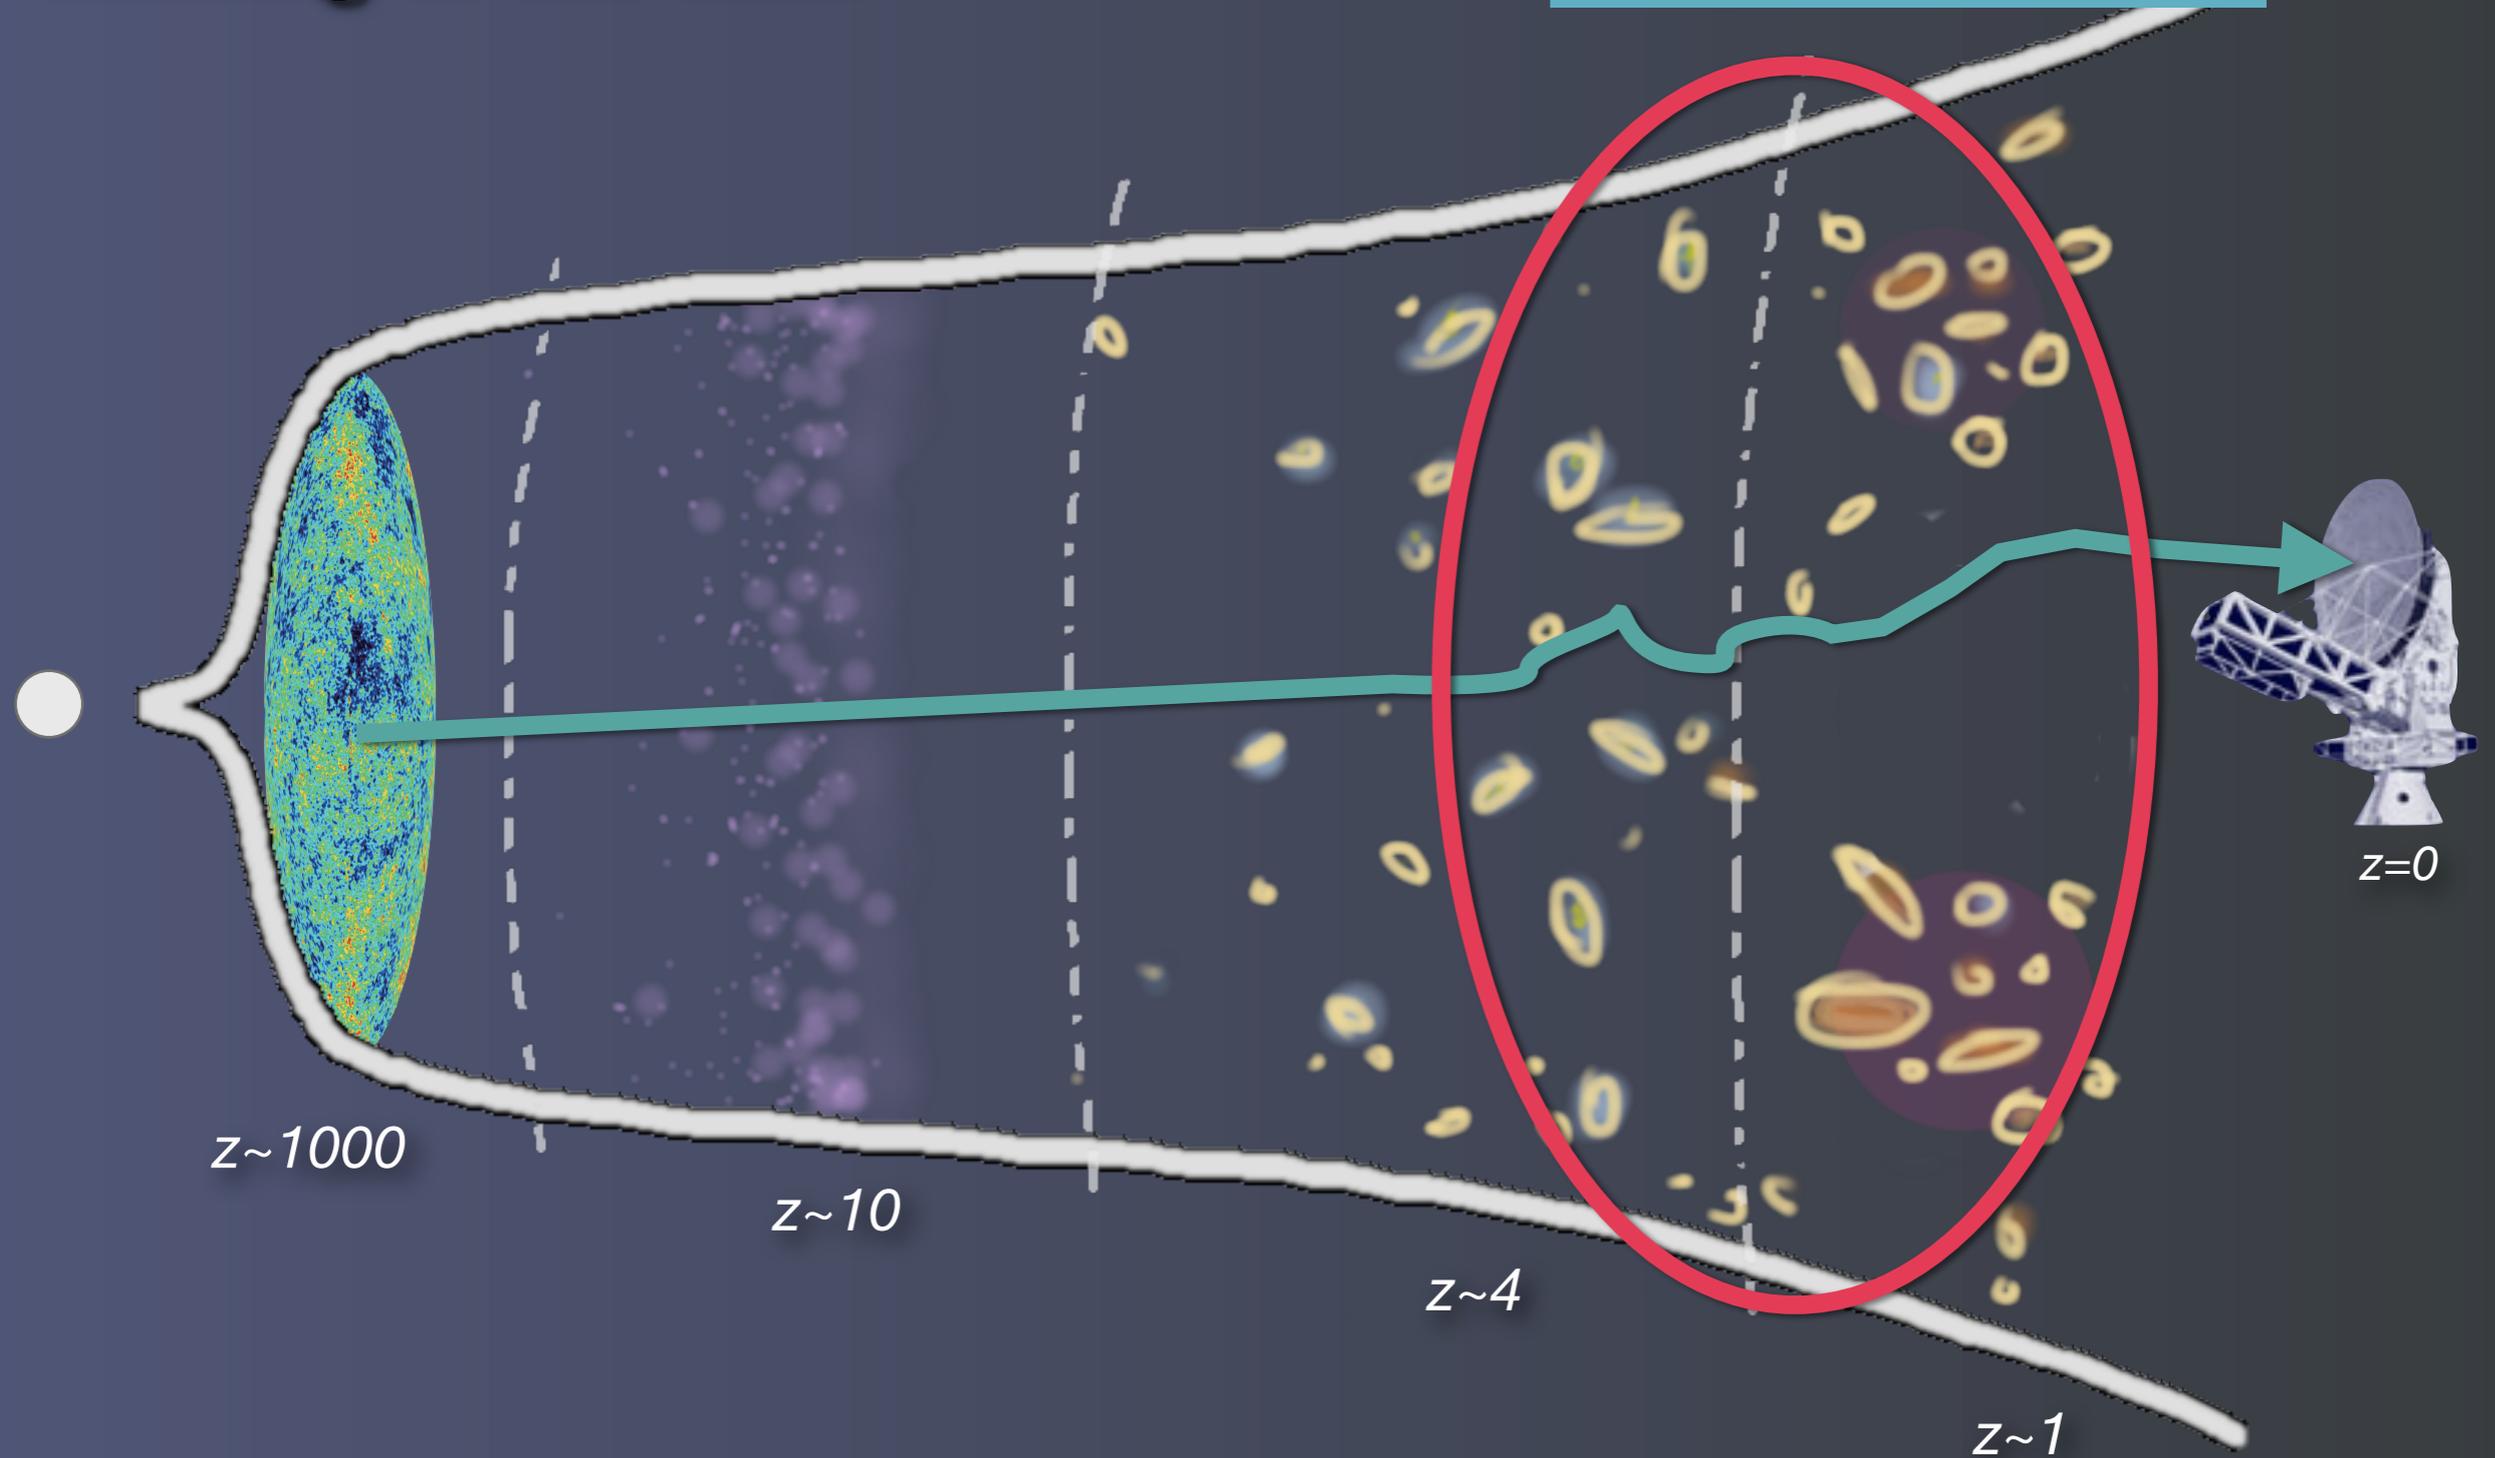

2. Results from SPT:

Power Spectra coming soon...

The first month of the full survey field already has a beautiful T map!

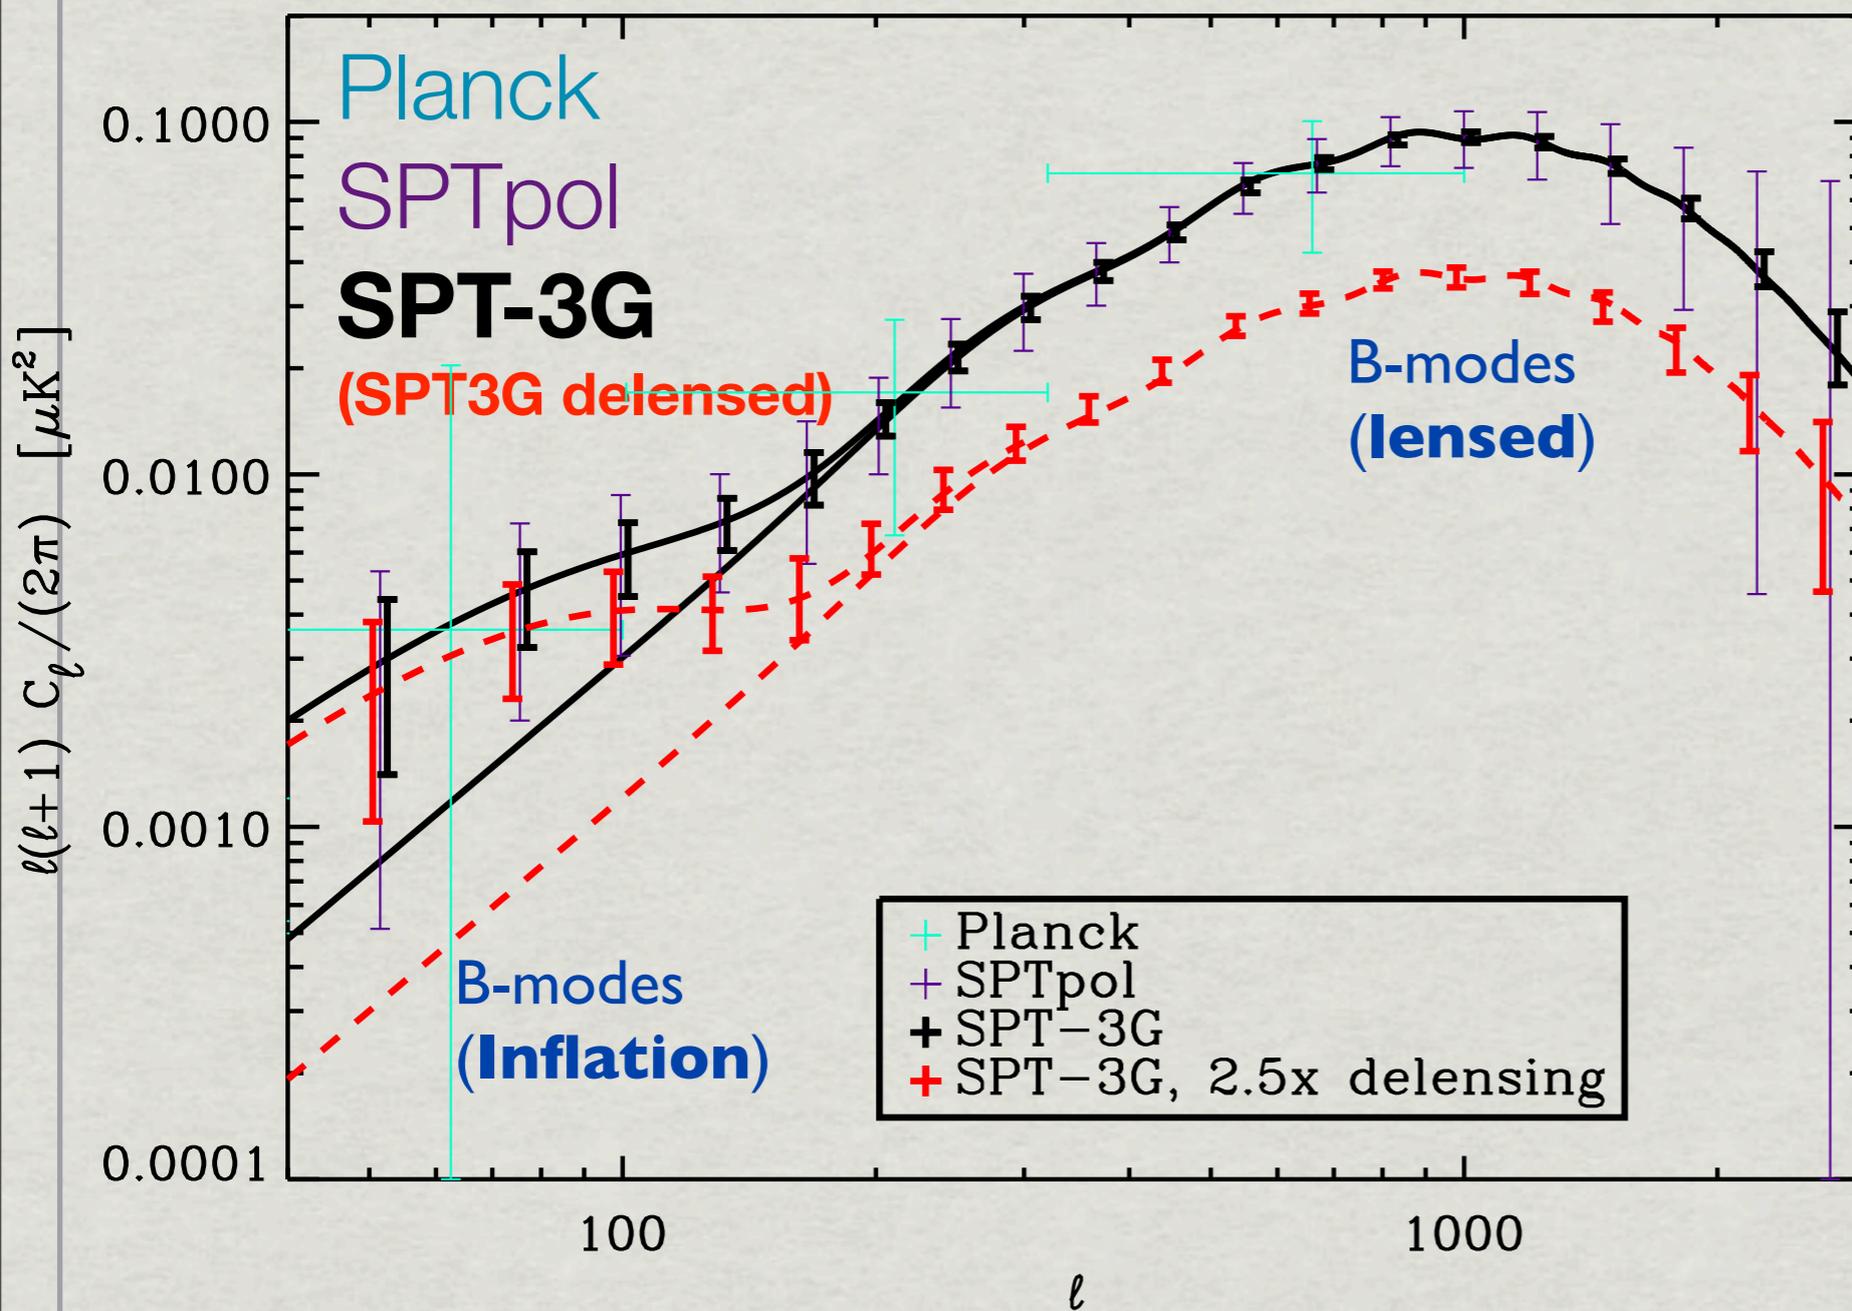

May 2013 data

SPTpol will make a strong detection of B-mode polarization.

SPT-3G: Projected B-mode Power Spectrum

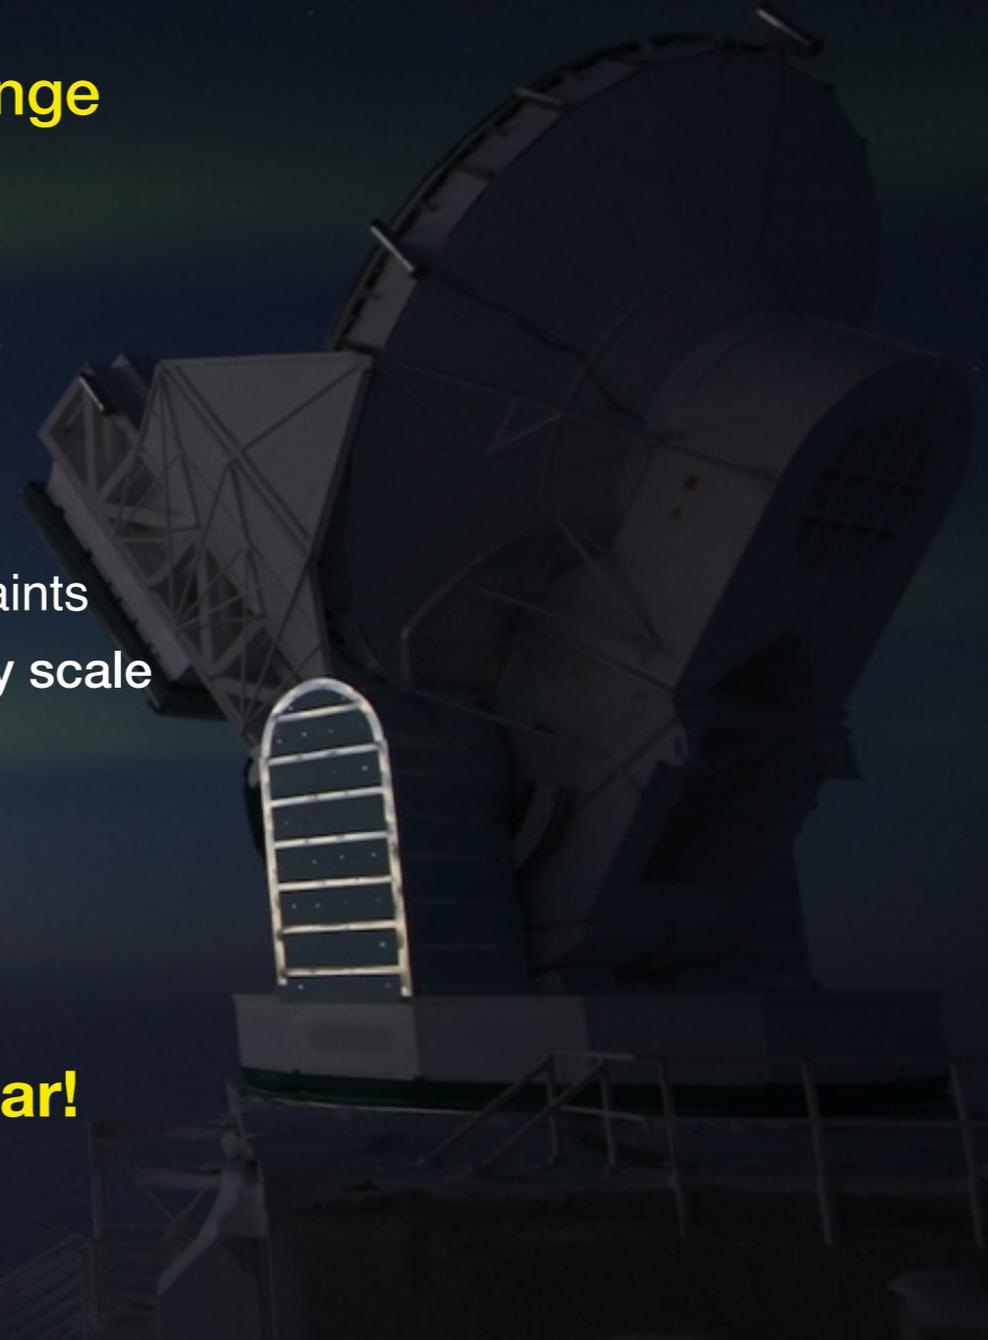

- Neutrino Constraints:
 - $\sigma(\Sigma m_\nu) = 0.06 \text{ eV}$
- “De-lens” the CMB at large-angular scales and improve “ r ” Inflation constraint
 - $\sigma(r) = 0.01$

Credit: T. Crawford

Summary

- **SPT-SZ survey complete with broad science impact:**
 - **High-redshift galaxies:** Early star and galaxy formation
 - **Distant, massive clusters:** Dark energy, neutrinos, cluster evolution
 - **Primordial CMB anisotropy:** Inflation, early universe physics
 - **CMB lensing:** “weighing” the universe, neutrinos
- **In conjunction with WMAP, SPT data probes a wide range of topics relevant to physics:**
 - primordial power spectra & inflation
 - neutrino mass
 - dark energy
- **SPTpol: 1.4 years into 4 year survey**
 - **Lensing “B”-modes:** Detection imminent, improve neutrino constraints
 - **Inflationary “B”-modes:** Improve constraints on inflation’s energy scale
- **SPT-3G: Development underway**
 - Observations begin in 2016
 - Inflation, Lensing (neutrino masses), Clusters, kSZ/tSZ
- **Expect first B-mode CMB polarization results this year!**
 - New window into inflation and structure growth at $z \sim 2$

Thank You!

Backup Slides

How does the CMB constrain N_{eff} ?

How many light, ν -like particle species are there?

from the Particle Data Group,
number of light ($m < \frac{m_Z}{2}$) particles that couple to the Z,

$$N_\nu = 2.984 \pm 0.0082 \text{ (LEP)}$$

A much less accurate, but more generic test can be done by measuring the *expansion rate* of the early, radiation-dominated universe (see e.g. Steigman, Schramm, Gunn 1976).

In this way, the abundance of BBN elements can be used to constrain N_ν :

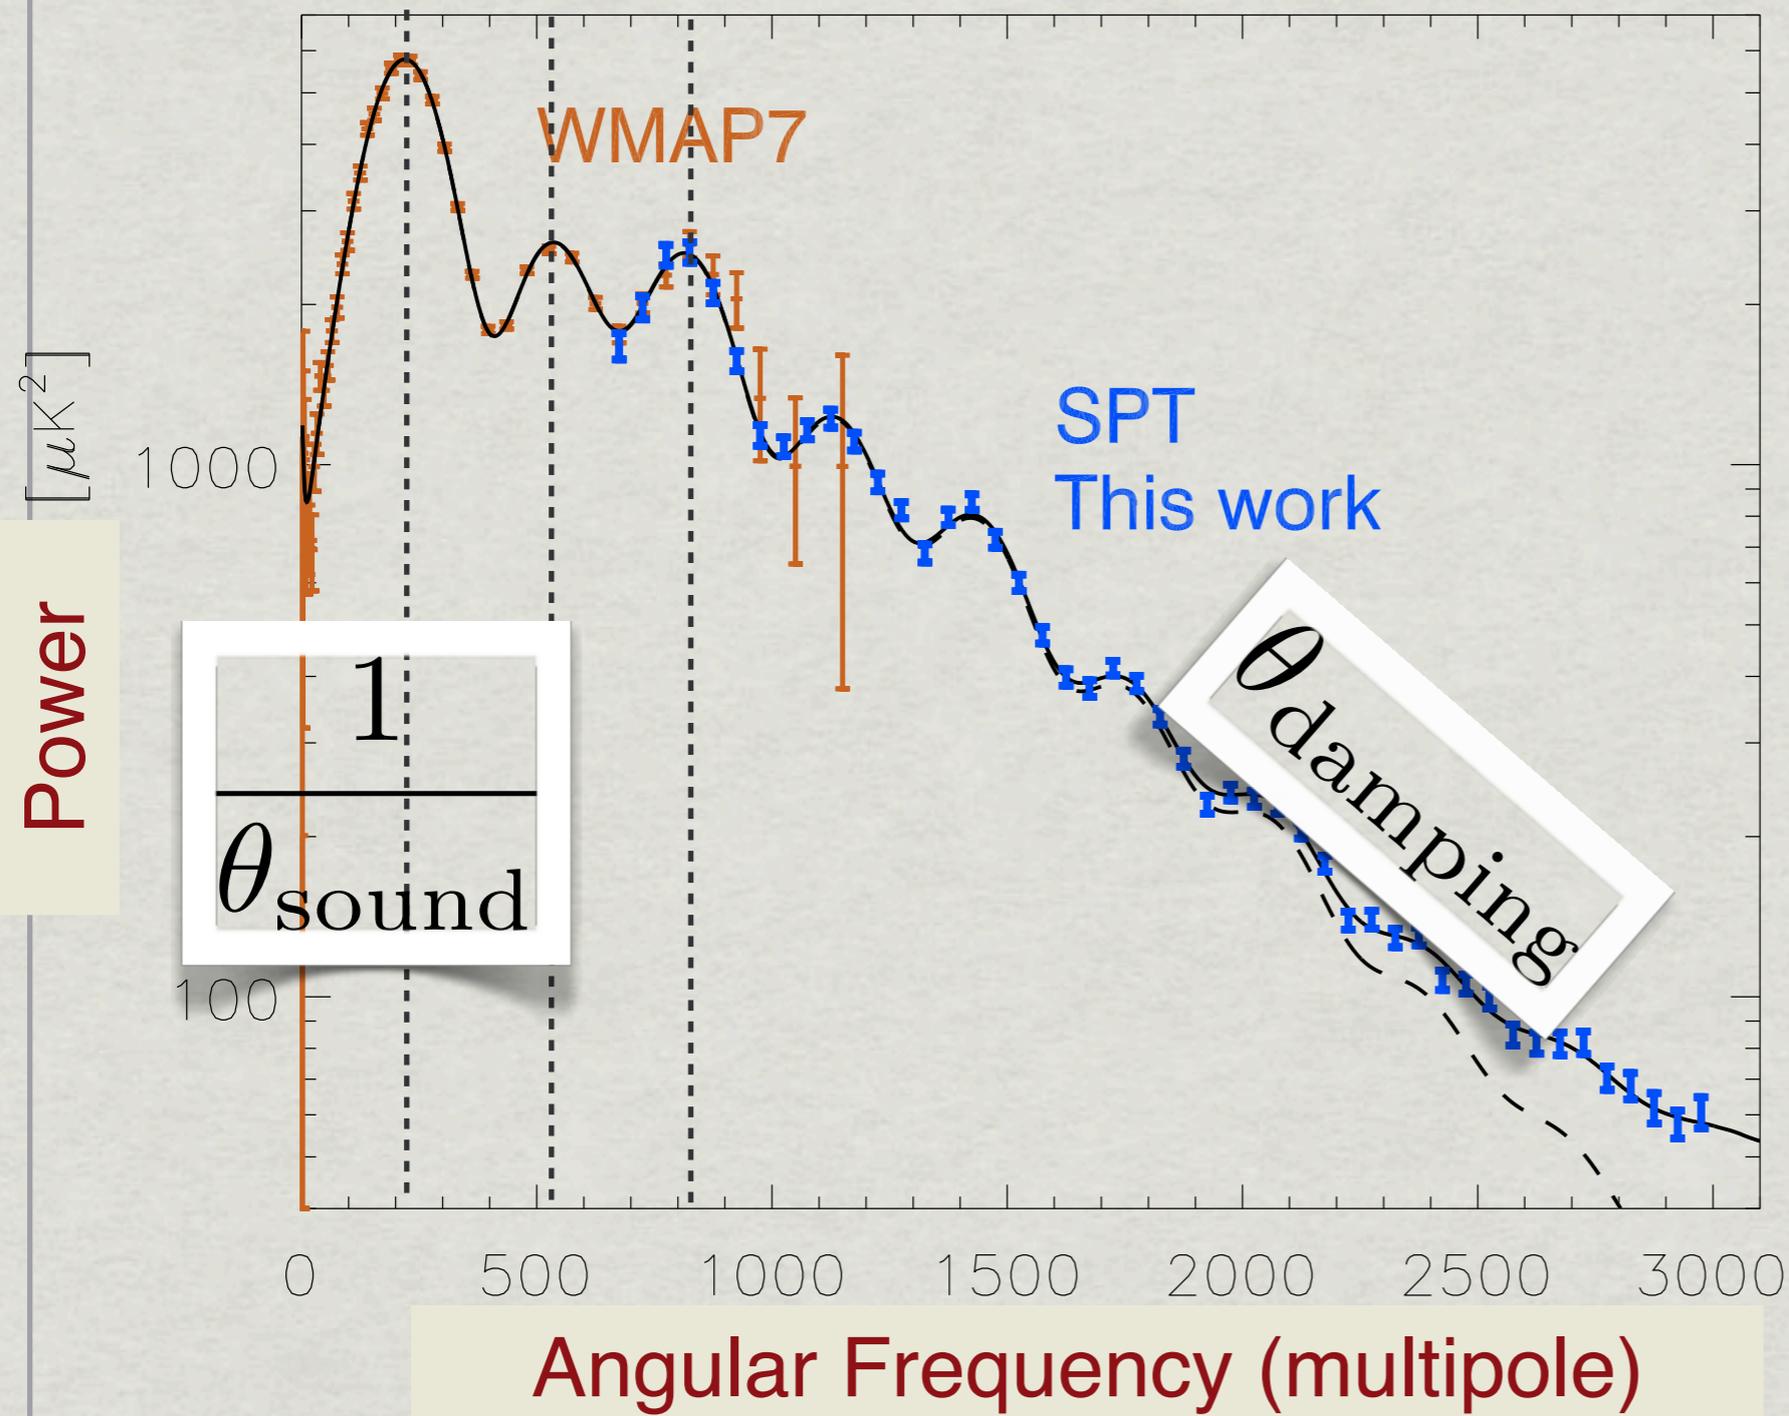

$$N_\nu = 3.82 \pm 0.45 \text{ (Izotov & Thuan)}$$

$$N_\nu = 3.13 \pm 0.21 \text{ (Peimbert et al)}$$

from Nollett &
Holder 2011

What about the CMB?

CMB sensitivity to N_ν

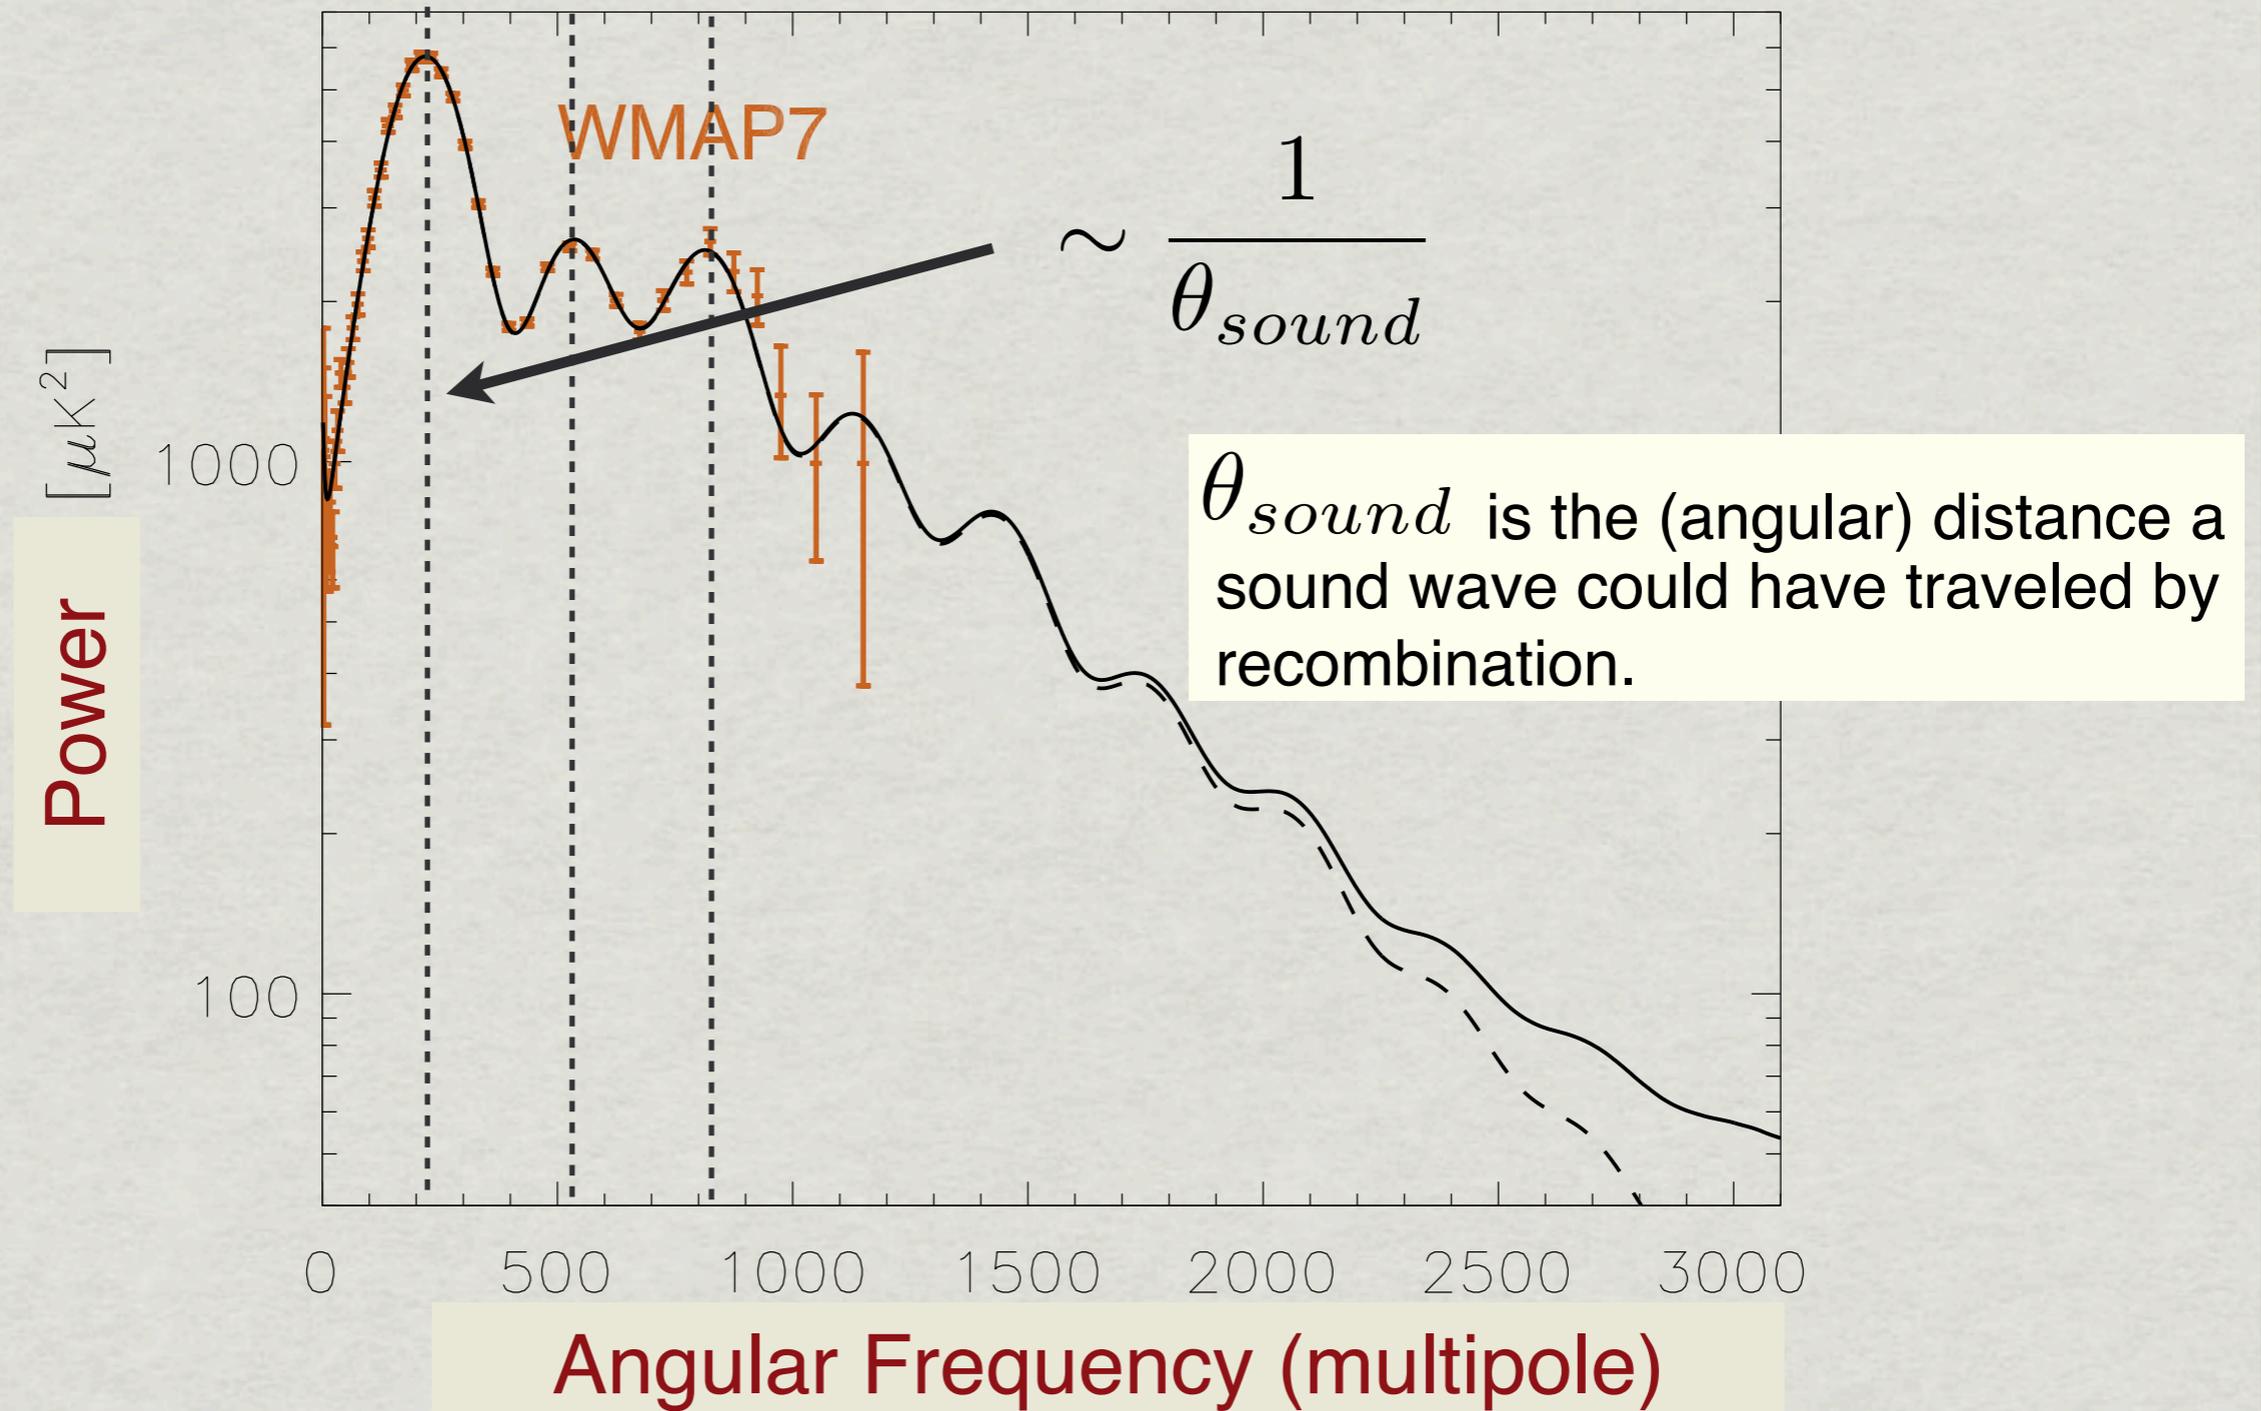

- The **number of relativistic species (think neutrinos)** present in the early universe affects the **expansion rate** during that time.

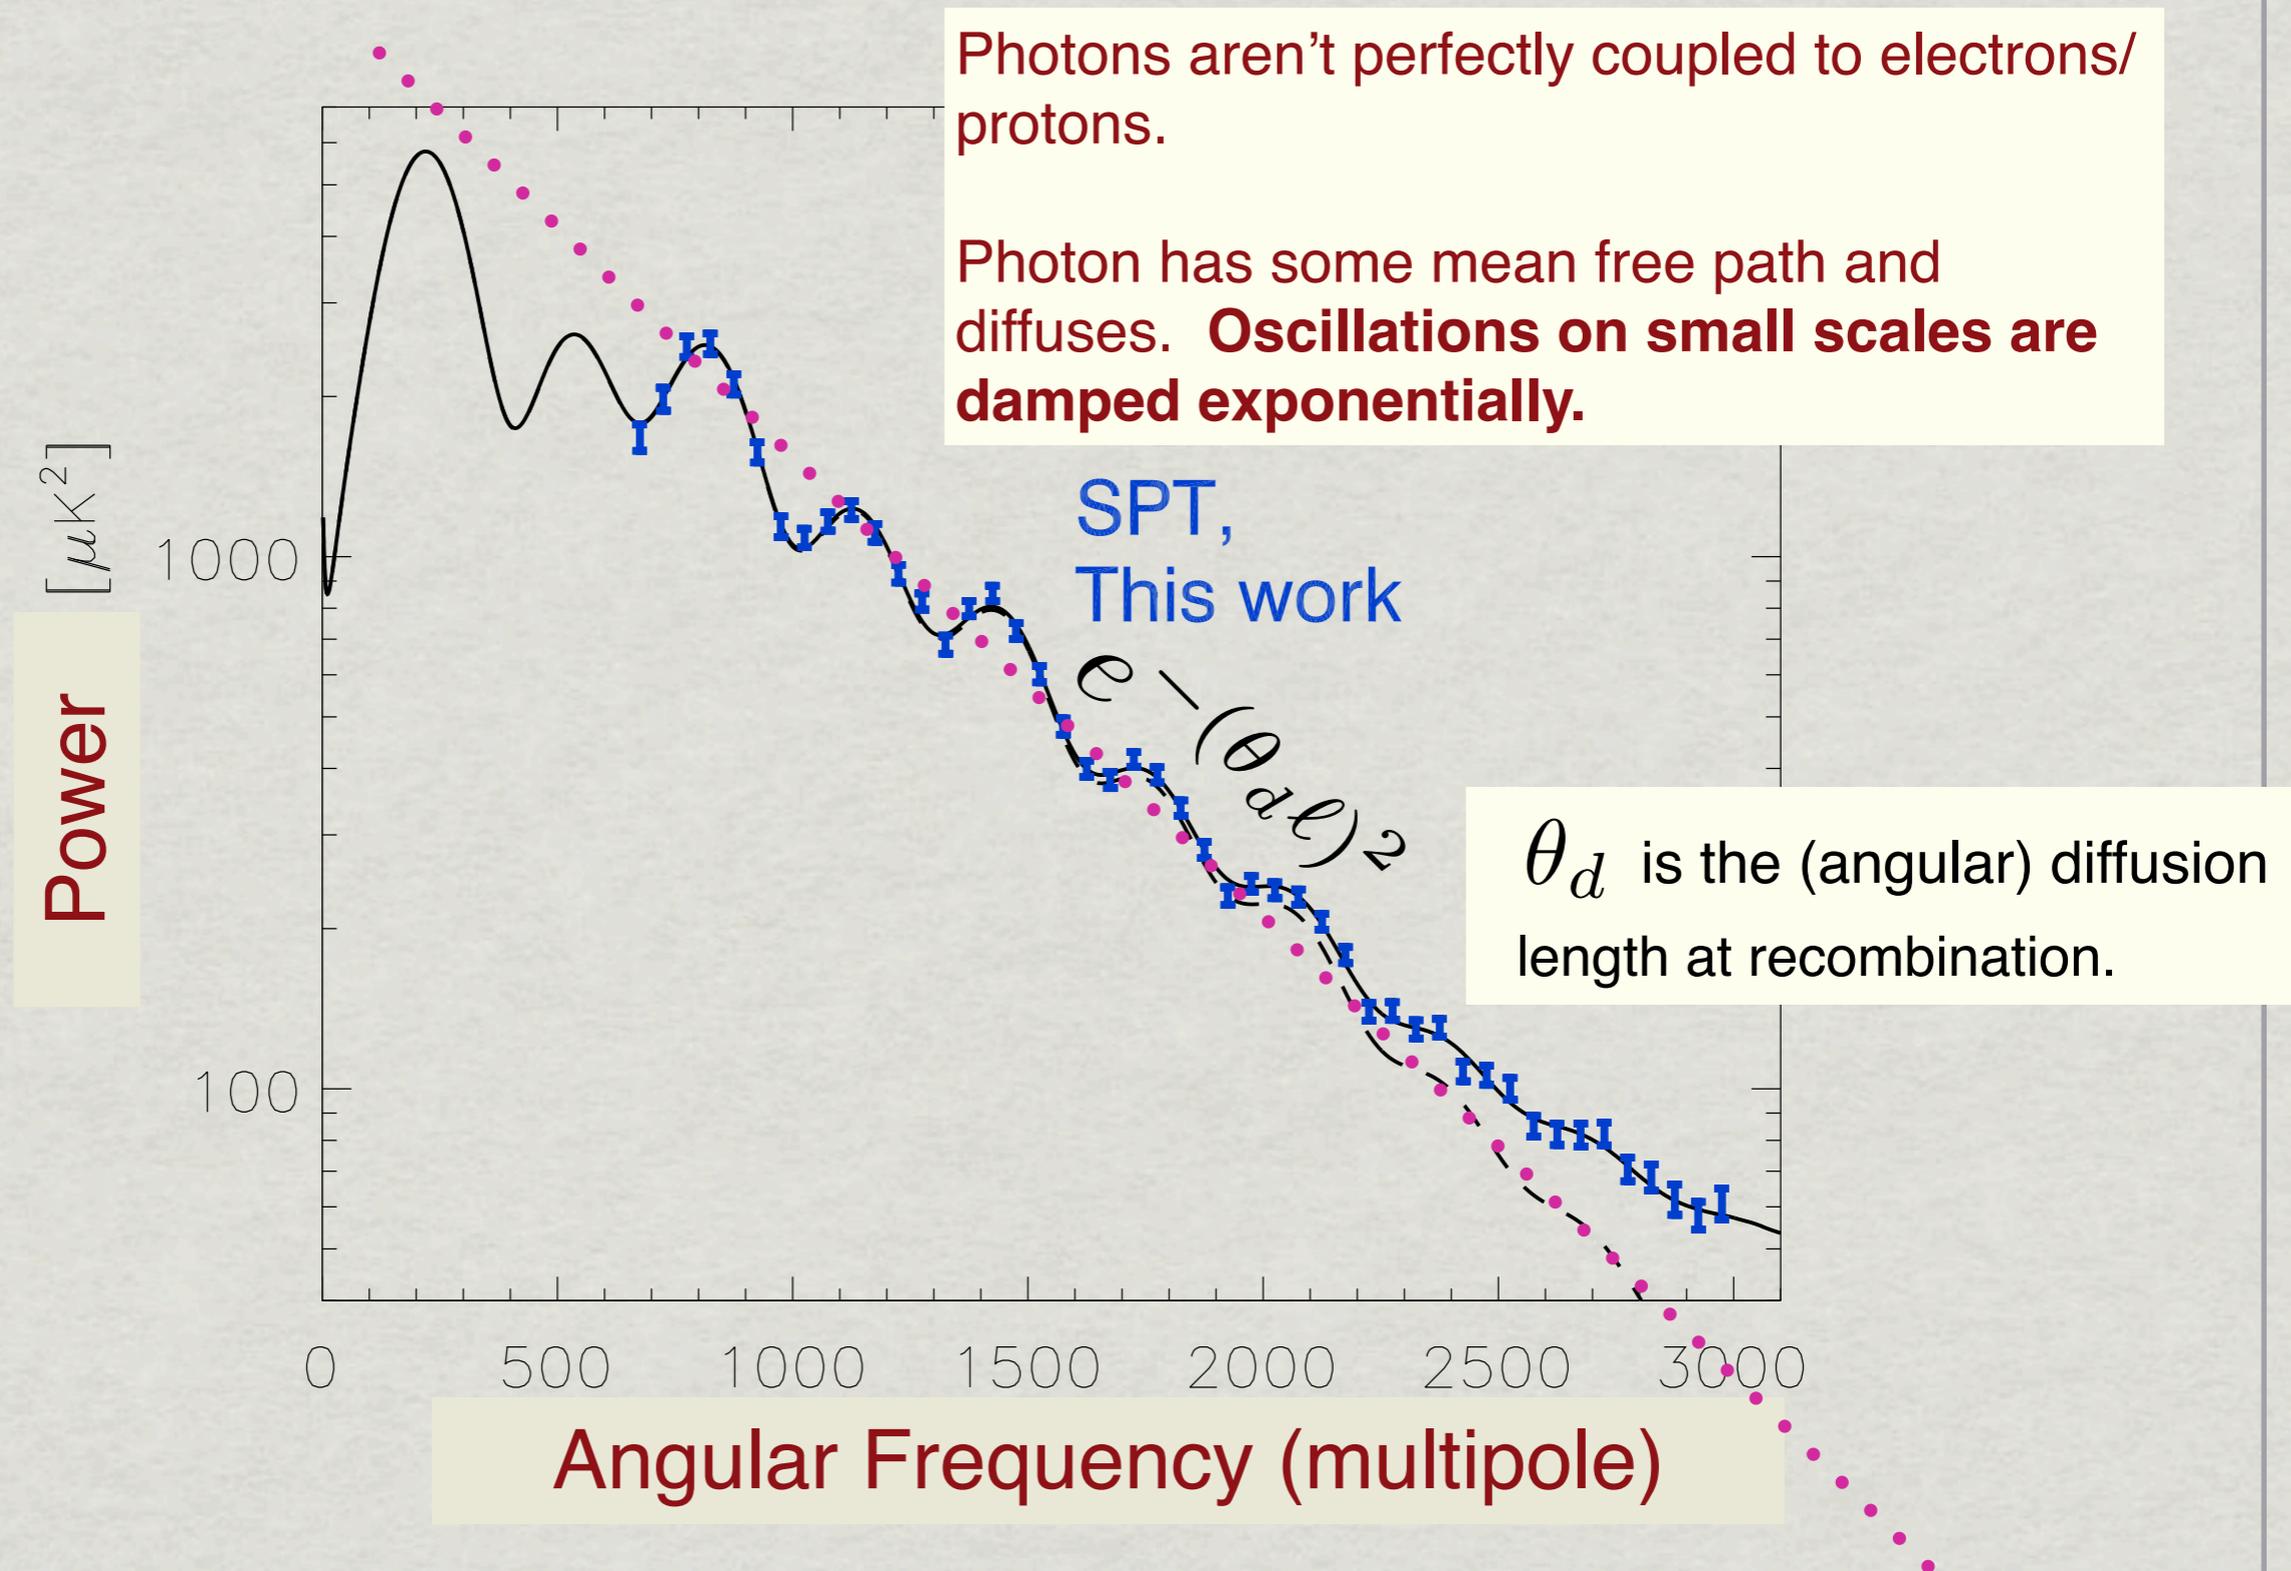

- The ratio $\frac{\theta_{\text{damping}}}{\theta_{\text{sound}}}$ is sensitive to the expansion rate.

- **SPT+WMAP can measure the number of relativistic species.** (3 neutrinos + ?)

The *Sound Scale*

The *Damping* Scale

Sensitivity to Neutrinos

How does an extra neutrino affect these CMB observables, θ_s and θ_d ?

1) An extra neutrino species **increases the expansion rate** during this \sim radiation-dominated era.

$$\left(\frac{\dot{a}}{a}\right)^2 \equiv H^2 \propto (\rho_\gamma + \rho_\nu + \rho_{\text{matter}} + \dots)$$

More neutrinos \Rightarrow higher density \Rightarrow faster expansion

Sensitivity to Neutrinos

2) Consider how the real space equivalents of sound scale r_s and damping scale r_d , depend on the expansion rate, H :

Sound Scale

$$r_s \propto \int_0^{a^*} \frac{c_s da}{a^2 H}$$

$$r_s \propto H^{-1} \propto \text{time}$$

Damping Scale

$$r_d^2 \propto \int_0^{a^*} \frac{da}{a^3 \sigma_T n_e H} \propto \frac{1}{H}$$

$$r_d \propto H^{-0.5} \propto \sqrt{\text{time}}$$

(diffusion process. random walk.)

$$\frac{r_d}{r_s} = \frac{\theta_d}{\theta_s} \propto H^{0.5}$$

(see e.g. 1104.2333, Z. Hou, RK, L. Knox, C. Reichardt)

Sensitivity to Neutrinos

$$\frac{r_d}{r_s} \propto H^{0.5} \propto (\rho_\gamma + \rho_\nu + \rho_m + \dots)^{0.25}$$

$$\frac{\theta_d}{\theta_s} \propto (\rho_\gamma + \rho_\nu + \rho_m + \dots)^{0.25}$$

- The ratio $\frac{\theta_d}{\theta_s}$ is measured well using the CMB.
- The photon density ρ_γ is well known from 3K temperature of CMB.
- The ratio $\frac{\rho_m}{\rho_\gamma + \rho_\nu} = 1 + z_{\text{EQ}}$ is also well measured using CMB.

We can solve for the neutrino density ρ_ν .

defining N_{eff}

N_{eff} is the *effective number of relativistic species*.

$$N_{\text{eff}} \equiv \frac{\rho_\nu}{\rho_\gamma} \left(\frac{8}{7} \left(\frac{11}{4} \right)^{4/3} \right)$$

The standard value is **$N_{\text{eff}} = 3.046$** .

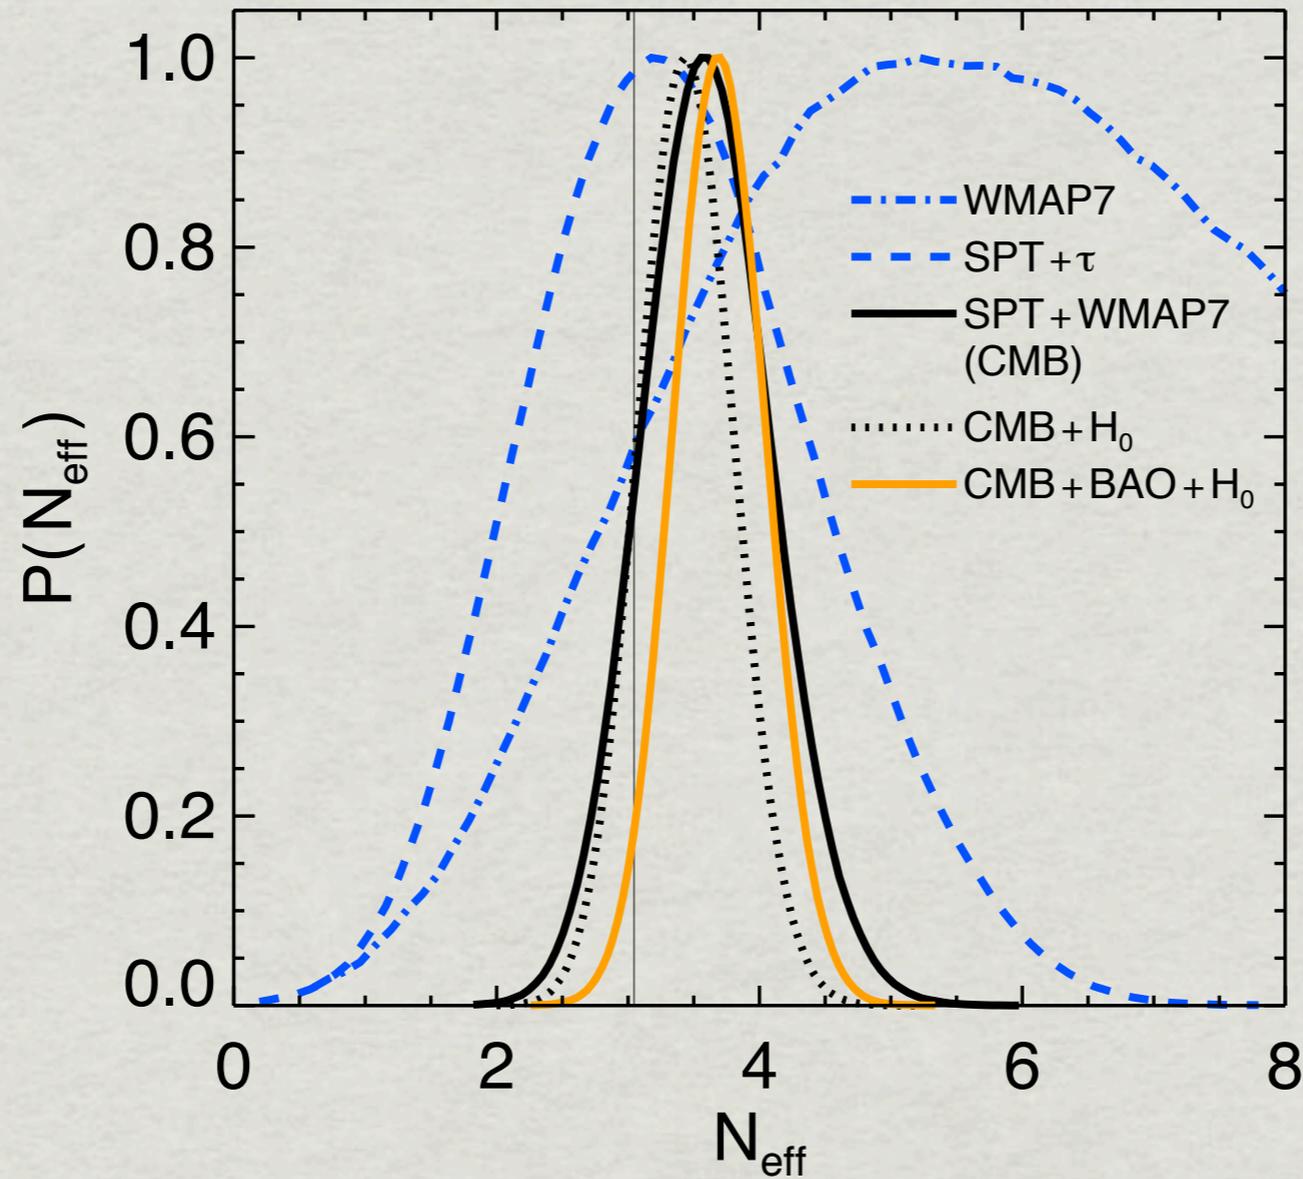

This is

3.000 for the 3 neutrino species,

0.046 for energy injected by electron/positron annihilation.

$N_{\text{eff}} > 3.046$ could correspond to a new particle species that is relativistic prior to recombination and has an energy density comparable to the standard neutrinos.

CMB Constraints on N_{eff}

- $N_{\text{eff}} = 3.62 \pm 0.48$ (SPT+WMAP) (1.2 σ higher than 3.046)
- $N_{\text{eff}} = 3.71 \pm 0.35$ (SPT+WMAP+ H_0 +BAO) (1.9 σ higher than 3.046)

WMAP 9-year

WMAP9 papers and new SPT paper came out within days of each other. CMB-only N_{eff} consistent with new SPT paper:

$$N_{\text{eff}} = 3.89 \pm 0.67 \text{ (WMAP9 + eCMB)}$$

$$N_{\text{eff}} = 3.62 \pm 0.48 \text{ (WMAP7 + new SPT)}$$

(“eCMB”
dominated by
old SPT data)

But differences in N_{eff} when BAO is included?

$$N_{\text{eff}} = 3.26 \pm 0.35 \text{ (WMAP9 + eCMB + H0+BAO)}$$

$$N_{\text{eff}} = 3.71 \pm 0.35 \text{ (WMAP7 + new SPT + H0+BAO)}$$

Huh?

WMAP 9-year

WMAP9 papers and new SPT paper came out within days of each other. CMB-only N_{eff} consistent with new SPT paper:

$$N_{\text{eff}} = 3.89 \pm 0.67 \text{ (WMAP9 + eCMB)}$$

$$N_{\text{eff}} = 3.62 \pm 0.48 \text{ (WMAP7 + new SPT)}$$

(“eCMB”
dominated by
old SPT data)

But differences in N_{eff} when BAO is included?

$$N_{\text{eff}} = 3.26 \pm 0.35 \text{ (WMAP9 + eCMB + H0 + BAO)}$$

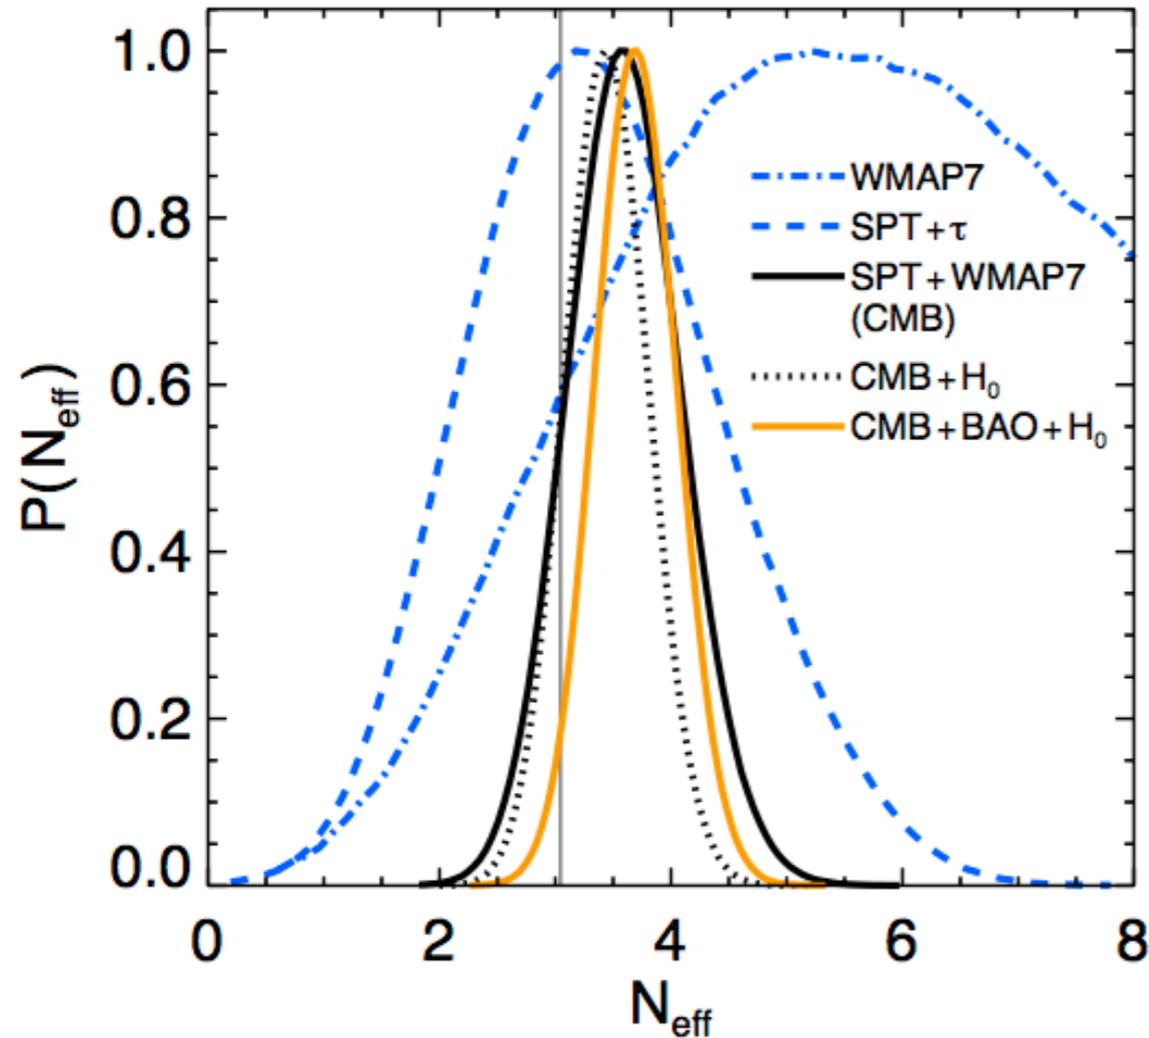

$$N_{\text{eff}} = 3.71 \pm 0.35 \text{ (WMAP7 + new SPT + H0 + BAO)}$$

Caused by bug in WMAP9 which shifted and artificially tightened constraint on N_{eff} when BAO data was used.

Regardless of bug, the new SPT papers provide the best constraints across the board, because they use the new SPT data, which WMAP9 Hinshaw et al did not.

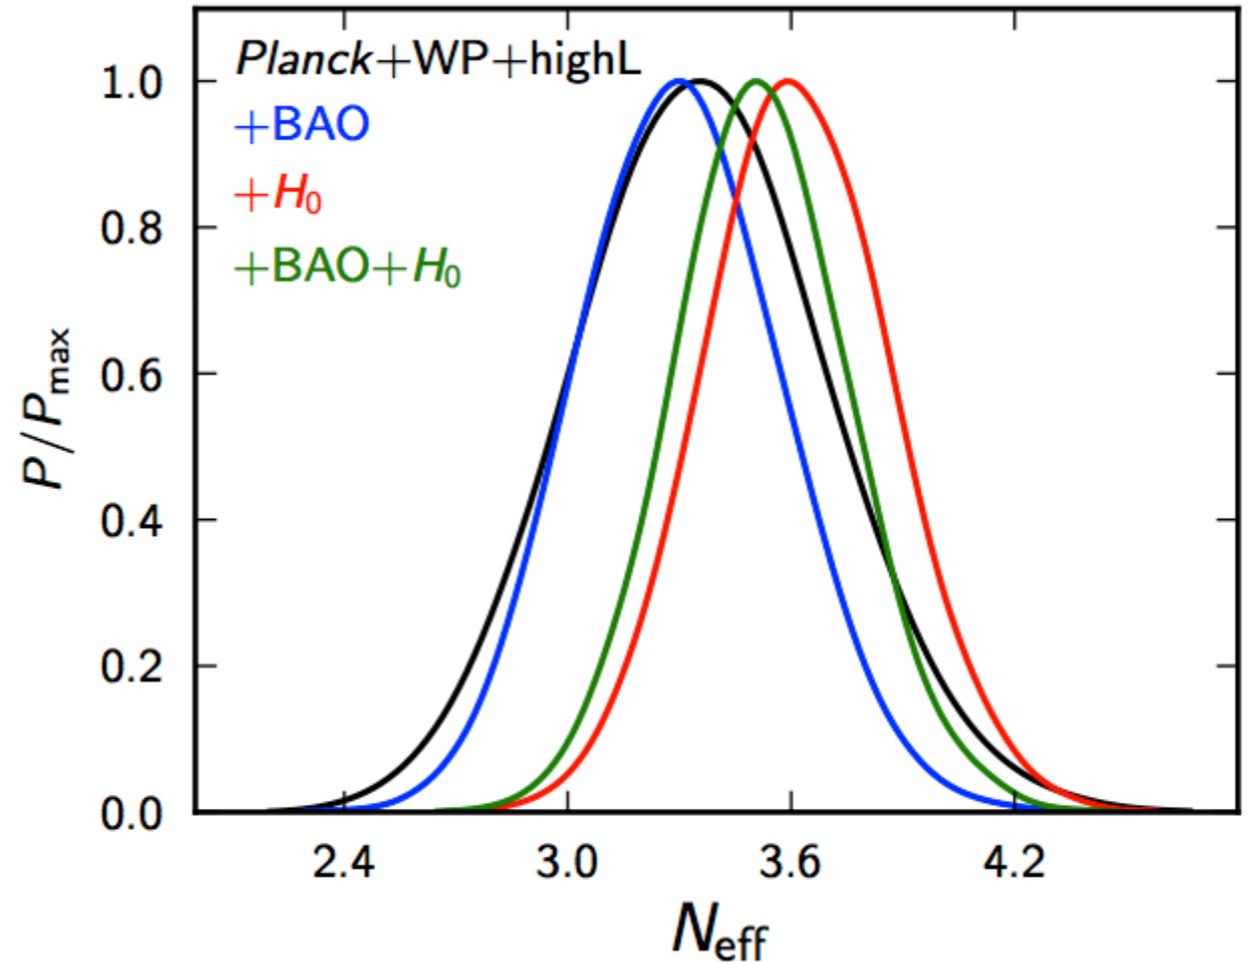

Furthermore, updating SPT results to include WMAP9 rather than WMAP7 shows no appreciable changes (preliminary).

CMB Constraints on N_{eff}

SPT + WMAP7:

$$N_{\text{eff}} = 3.62 \pm 0.48$$

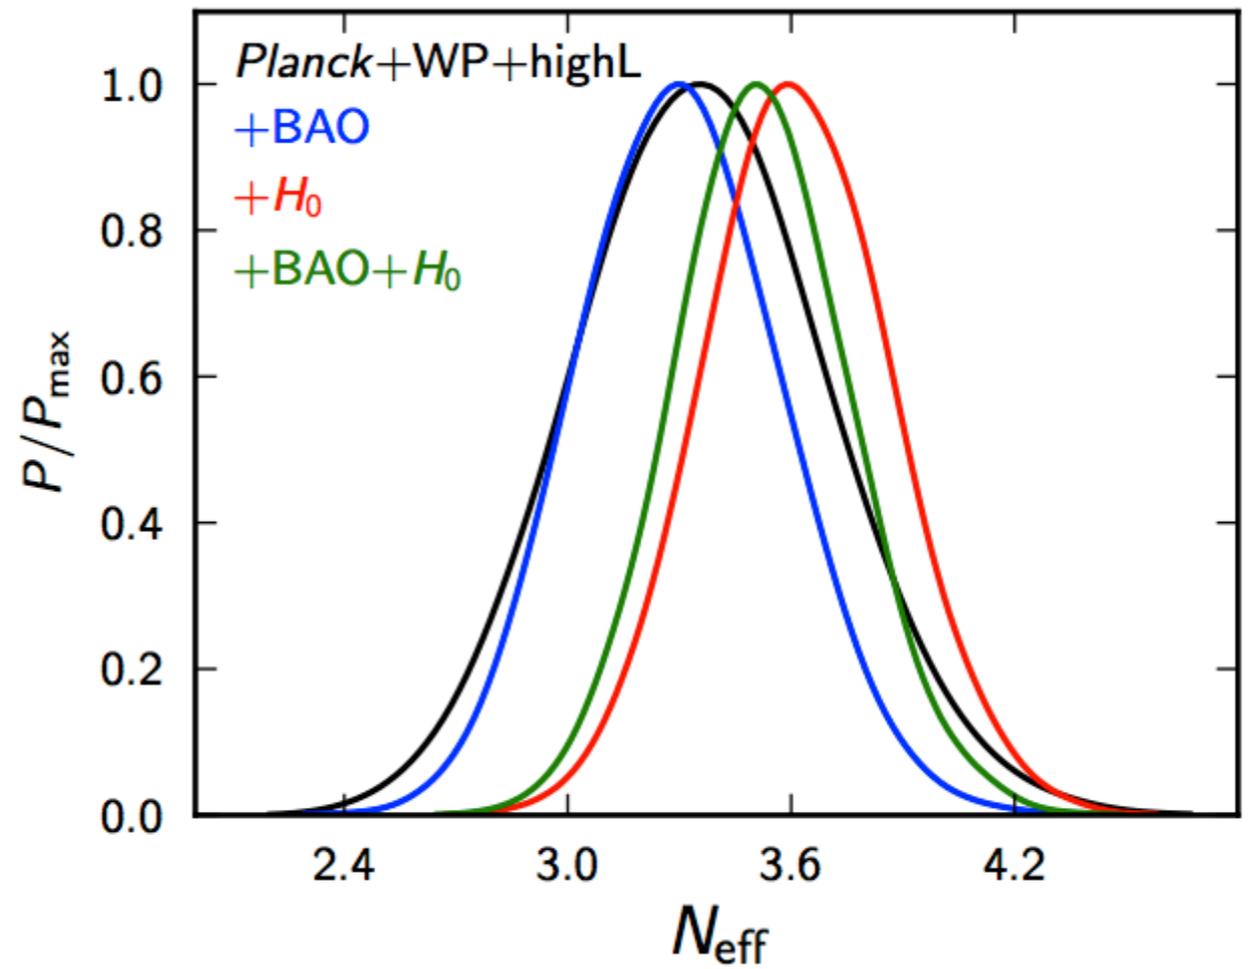

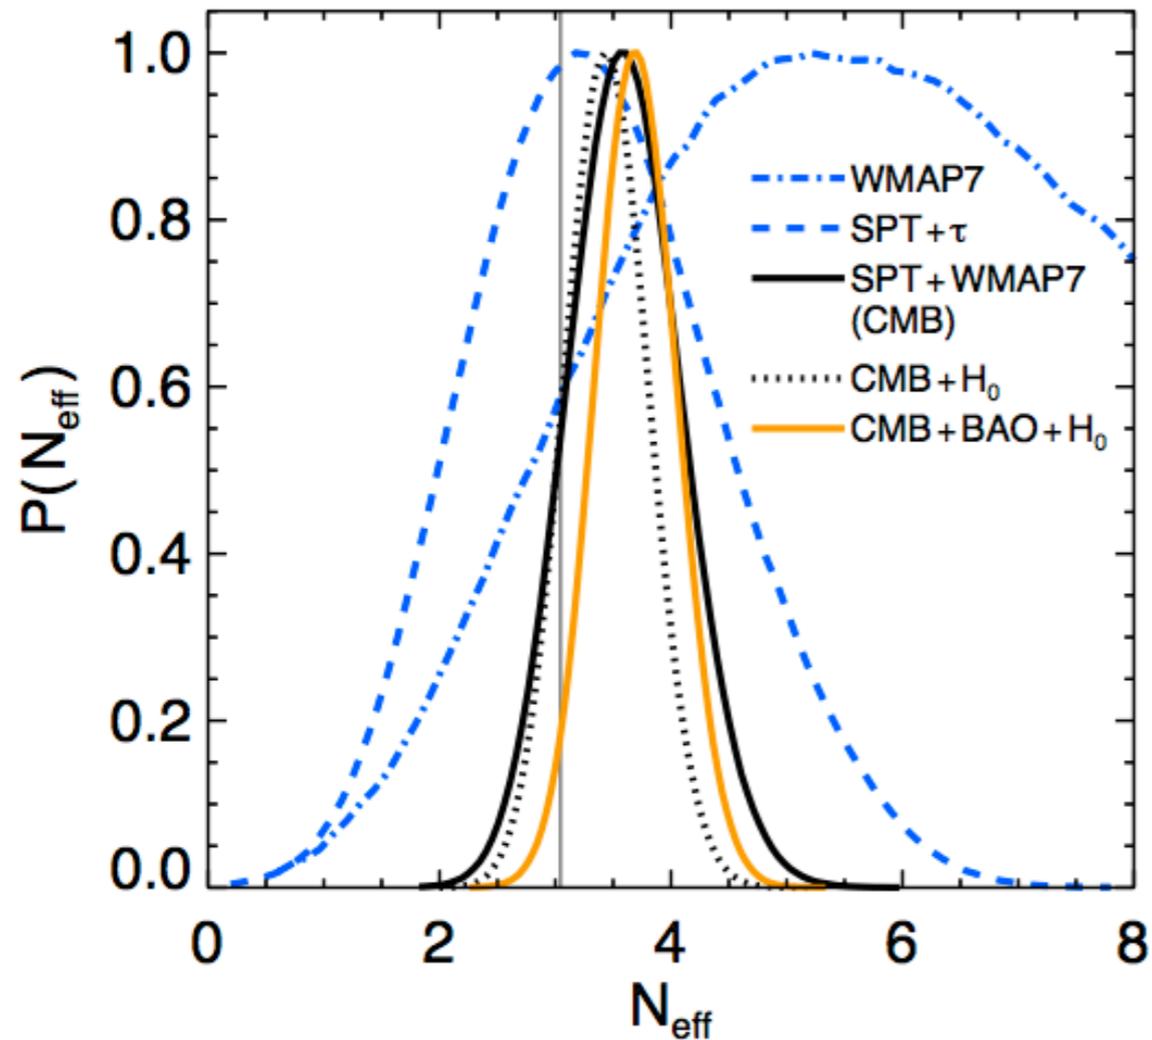

Planck + WP + highL:

$$N_{\text{eff}} = 3.36 \pm 0.34$$

- Planck and SPT are consistent with each other, and the Λ CDM prediction.

CMB Constraints on N_{eff}

SPT + WMAP7:

$$N_{\text{eff}} = 3.62 \pm 0.48$$

Planck + WP + highL:

$$N_{\text{eff}} = 3.36 \pm 0.34$$

$$N_{\text{eff}} = 3.71 \pm 0.35$$

Add BAO+ H_0

$$N_{\text{eff}} = 3.52 \pm 0.24$$

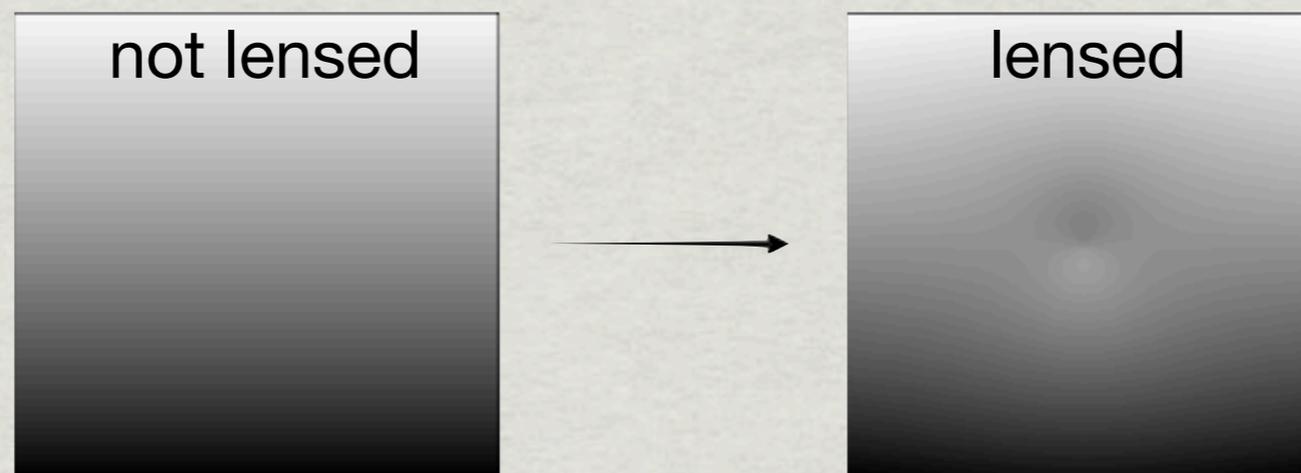

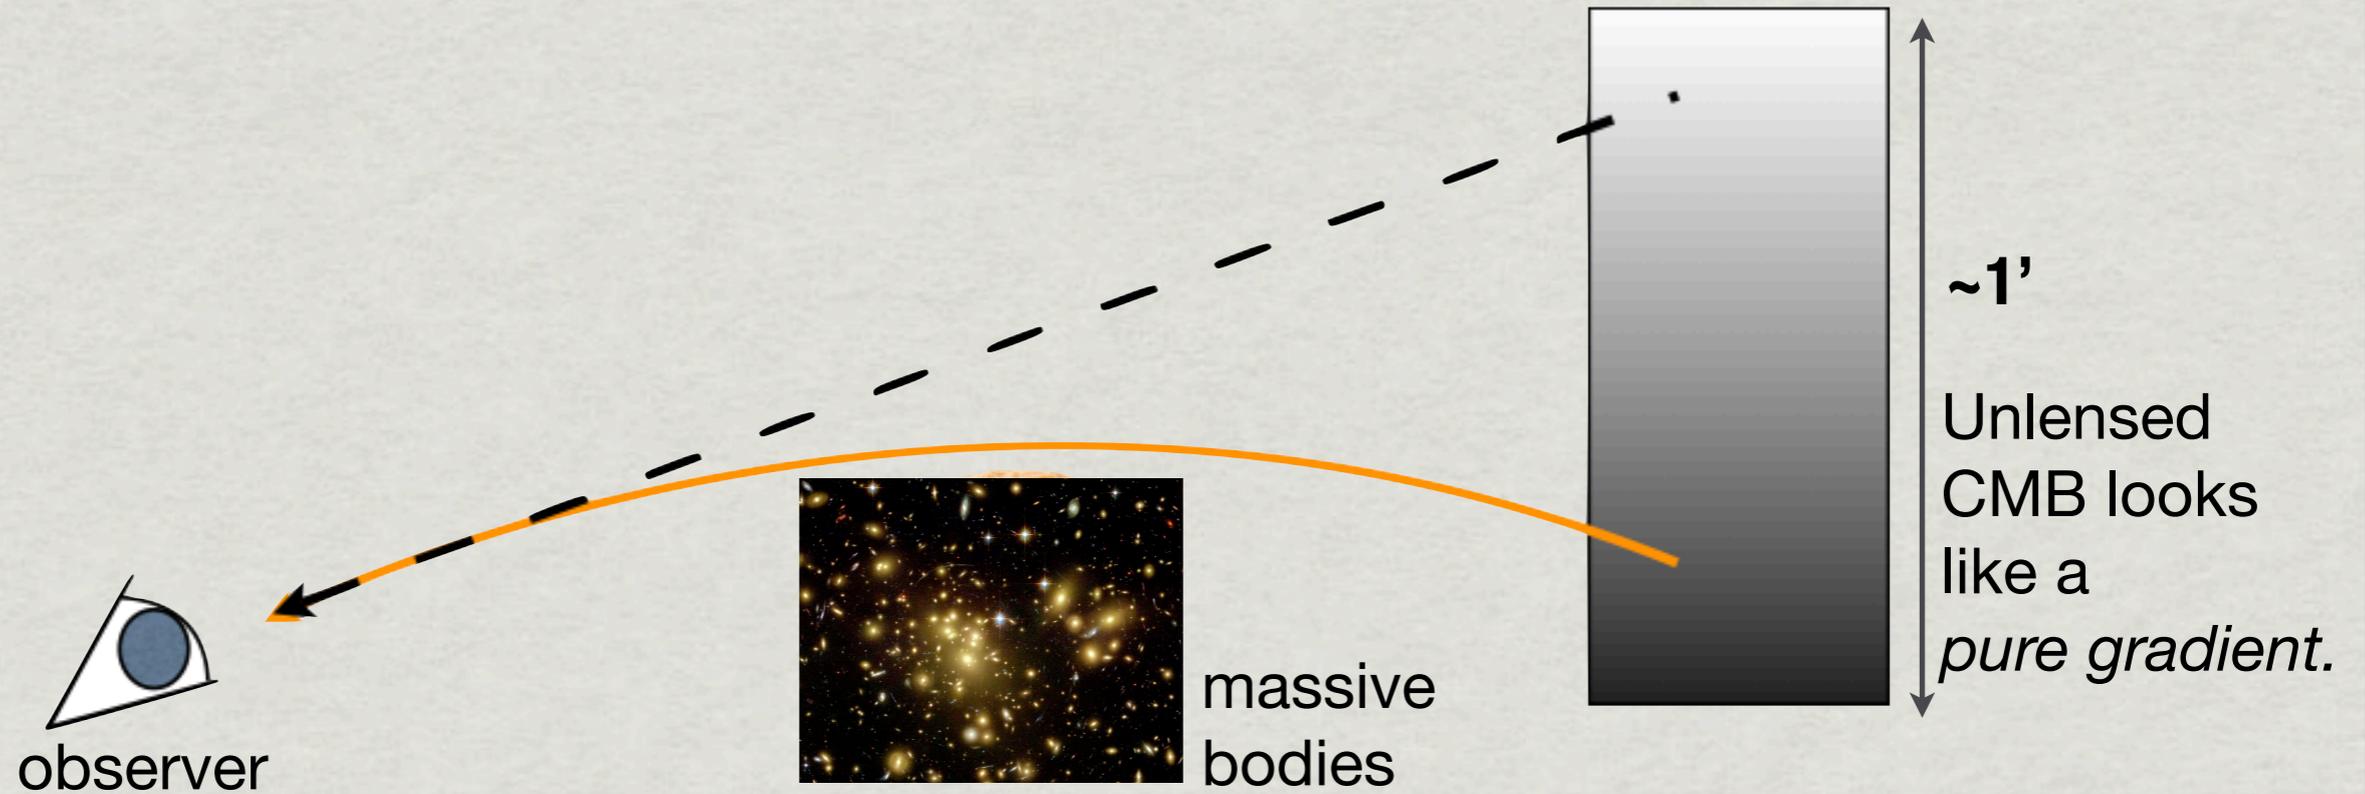

Take Away #v

CMB data that measures $\frac{\theta_d}{\theta_s}$ can constrain the number of neutrinos, due to the sensitivity of that ratio to the expansion rate prior to recombination.

Understanding the Quadratic Estimator

II. Mass Reconstruction

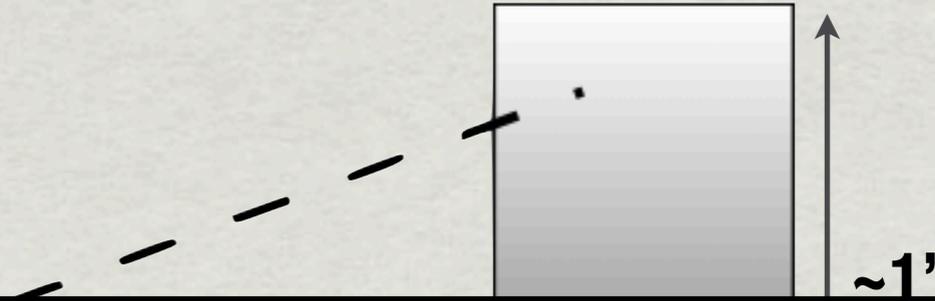

(more powerful, more complicated)

Small-scale wiggles are correlated with large-scale gradient.

II. Mass Reconstruction

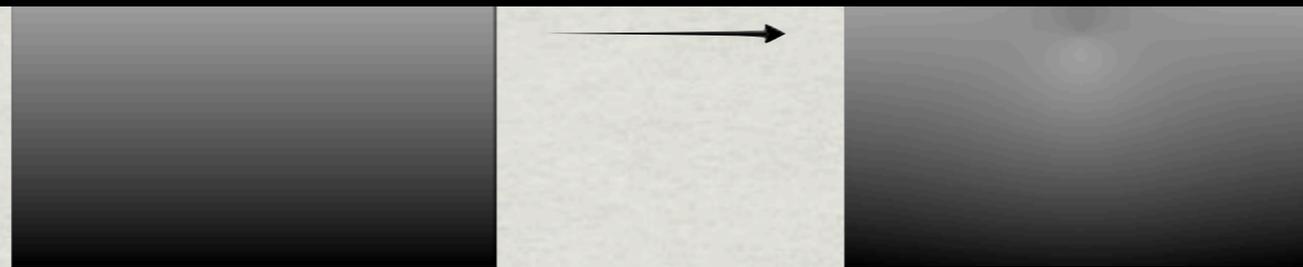

(more powerful, more complicated)

We can use this signature to **image the mass along the LOS to the CMB.**

One method (optimal, unbiased):
the “Quadratic Estimator”

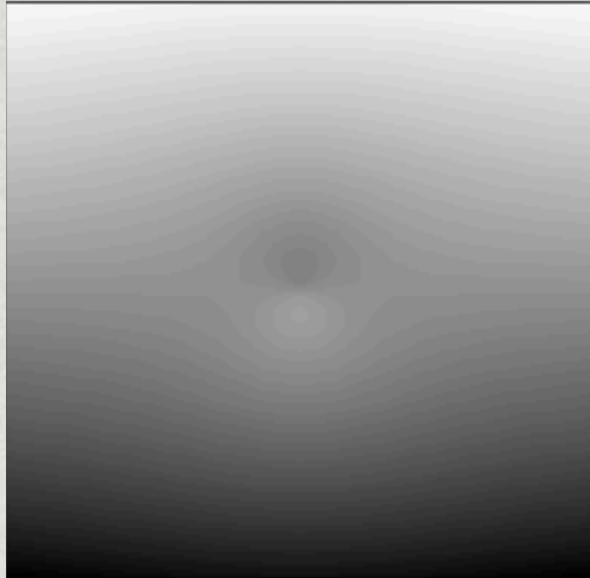

(see, e.g. W. Hu 2001; Hu & Okamoto 2002; Okamoto & Hu 2003)

Small-scale wiggles are correlated with large-scale gradient.

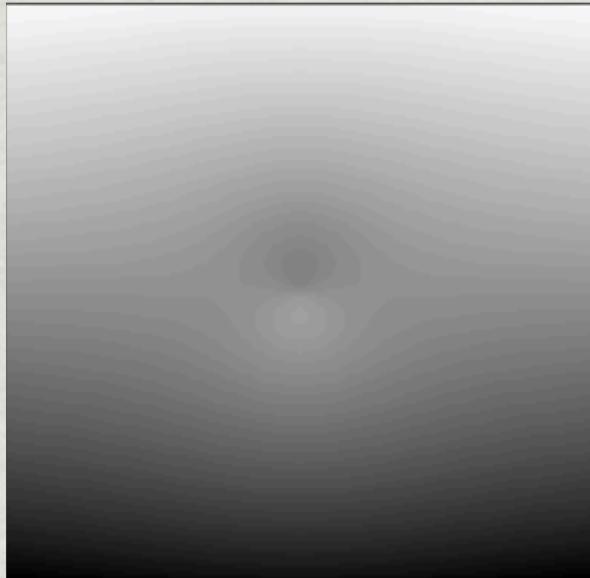

Unpacking the *Quadratic Estimator*

1.

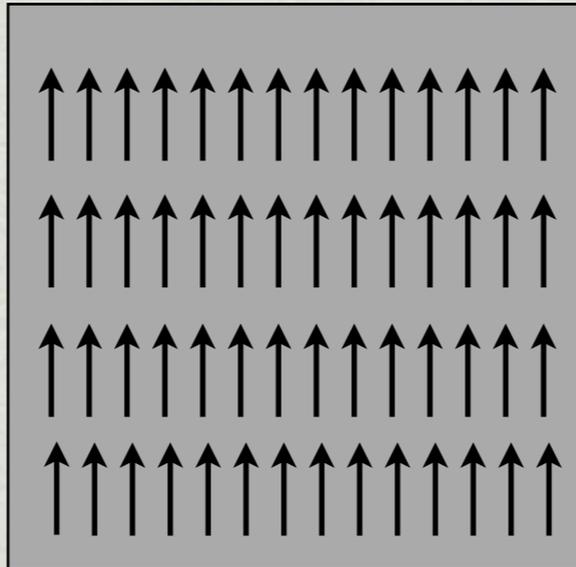

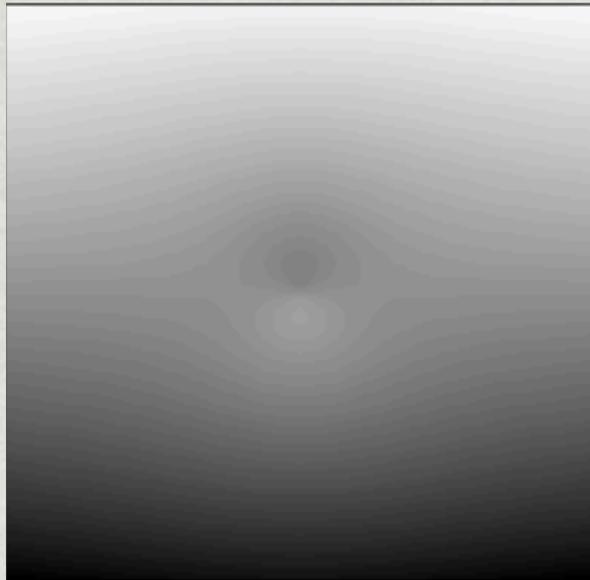

Start with **two** copies of your CMB temperature image.

2.
